

FINITENESS OF THE HOFER-ZEHNDER CAPACITY OF NEIGHBORHOODS OF SYMPLECTIC SUBMANIFOLDS

GUANGCUN LU

ABSTRACT. We use the minimal coupling procedure of Sternberg and Weinstein and our pseudo-symplectic capacity theory to prove that every closed symplectic submanifold in any symplectic manifold has an open neighborhood with finite (π_1 -sensitive) Hofer-Zehnder symplectic capacity. Consequently, the Weinstein conjecture holds near closed symplectic submanifolds in any symplectic manifold.

1. INTRODUCTION AND RESULTS

The existence of periodic orbits of Hamiltonian flows near a closed symplectic submanifold was recently studied by several authors, (cf. [2, 6, 11, 23, 35]). This question is closely related to the following:

Question 1.1. Does every compact symplectic submanifold B in any symplectic manifold (M, ω) have a neighborhood with finite (π_1 -sensitive) Hofer-Zehnder symplectic capacity?

A positive answer to Question 1.1 has some nice applications in symplectic topology and Hamiltonian dynamics. For example, it directly implies the existence of (contractible) Hamiltonian periodic orbits on a generic hypersurface near the symplectic submanifold. For a closed symplectic submanifold B of a geometrically bounded symplectic manifold (M, ω) , if (M, ω) is *symplectically aspherical*, that is, $\omega|_{\pi_2(M)} = 0$ and $c_1(TM)|_{\pi_2(M)} = 0$, Cieliebak, Ginzburg and Kerman [2] used symplectic homology to show that for a smooth function $H : M \rightarrow \mathbb{R}$ which attains an isolated minimum on B , the levels $\{H = \epsilon\}$ carry contractible periodic orbits for a dense set of small values $\epsilon > 0$. Under the same assumptions, it was proved by Ginzburg and Gürel in [6] that for a sufficiently small neighborhood U of B , there is a constant $C = C(U)$ such that the Hamiltonian flow of every smooth function H supported in U with $\min_B H > C$ has a nontrivial contractible periodic orbit of

period less than or equal to one. In [25, Corollary 1.3], Macarini showed that for a closed symplectic submanifold B of any geometrically bounded symplectic manifold (M, ω) , there exists a neighborhood U of B in M such that if H is a proper Hamiltonian on U and constant on B , then H has periodic orbits with contractible projection on B on almost all energy levels. Recently, Schlenk [35] generalized Hofer's energy-capacity inequality and used it to prove that for a closed submanifold B in geometrically bounded and stably strongly semi-positive symplectic manifolds, if either $\dim B < \operatorname{codim} B$, or $\dim B = \operatorname{codim} B$ and B is not Lagrangian, then B has a small open neighborhood with finite (π_1 -sensitive) Hofer-Zehnder capacity. In [23], the author introduced the pseudo symplectic capacity theory and used it to answer affirmably Question 1.1 for any closed symplectic submanifold of codimension two in any symplectic manifold.

Very recently, motivated by these and a very useful formula for the Hofer-Zehnder symplectic capacity of the product of a symplectic manifold and the standard symplectic ball, (cf. [4, 8, 15, 16, 23, 30]), Kerman [11] proposed the following.

Question 1.2. Let B be a closed symplectic submanifold of a symplectic manifold (M, ω) , and let U_R be a symplectic tubular neighborhood of B with (sufficiently small) radius R . Is the Hofer-Zehnder capacity of U_R equal to πR^2 ?

Here U_R is defined as follows. Let $\pi : (E, \sigma_E) \rightarrow B$ be the symplectic normal bundle of B in (M, ω) , and $J_E \in \mathcal{J}(E, \sigma_E)$, where $\mathcal{J}(E, \sigma_E)$ is the space of all complex structures on the vector bundle $E \rightarrow B$ compatible with σ_E , (cf. [29, page 69]). Denote by $g_E = \sigma_E \circ (1 \times J_E)$ the Hermitian metric on E . Then with a Hermitian connection ∇ on E , one can extend a canonical fiberwise 1-form α_E on $E \setminus B$ defined by $\alpha_E(b, v)(\cdot) = g_E(v, v)^{-1} \sigma_E(b)(v, \cdot)$ to a genuine 1-form α on $E \setminus B$. In [11], $U_R = \{(b, v) \in E \mid g_E(b)(v, v) \leq R^2\}$ equipped with the symplectic form $\omega|_B + d(g_E(v, v)\alpha)$ was called a *symplectic tubular neighborhood* of B .

Clearly, by Weinstein's symplectic neighborhood theorem, Question 1.2 implies Question 1.1 since U_R is symplectomorphic to a neighborhood of B in (M, ω) for $R > 0$ small enough. Using Floer homology, Kerman [11] affirmably answered Question 1.2 for the closed symplectic submanifold B of dimension $2m$ and codimension $2k$ in a geometrically bounded, symplectically aspherical manifold (M, ω) whose unit normal bundle $S(E)$ is homologically trivial in degree $2m$ in the sense that $H_{2m}(S(E), \mathbb{Z}_2) = H_{2m}(B, \mathbb{Z}_2) \oplus$

$H_{2(m-k)+1}(B, \mathbb{Z}_2)$. Actually Questions 1.1, 1.2 may be viewed as special cases of a general question: *how to compute the symplectic capacities of a symplectic fibration equipped with a compatible symplectic form*, which was proposed by C. Viterbo to the author during his visit to Institut des Hautes Études Scientifiques (IHES) in Spring 1999.

The proof of in [23, Theorem 1.24], which was partially motivated by [1, 31], consists of three steps. The first step is to construct a suitable projective bundle over the submanifold and a symplectic form on the total space of the projective bundle such that the symplectic submanifold has a neighborhood symplectomorphic to that of the zero section in the projective bundle. Then we proved that the total space of the projective bundle is symplectically uniruled with respect to the chosen symplectic form. Finally, the desired result follows from the properties of our pseudo symplectic capacity developed in that paper. Since we there considered the symplectic submanifold B of codimension two, its symplectic normal bundle has real rank 2, and thus may be viewed a (complex) line bundle. The projectivized bundle of the sum of the latter and trivial complex line bundle is a $\mathbb{C}P^1$ -bundle, and it is not hard to construct a symplectic form on the total space of it for which this $\mathbb{C}P^1$ -bundle is symplectically uniruled and naturally contains B as a symplectic submanifold with the symplectic normal bundle being isomorphic to that of B in the original symplectic manifold. For the symplectic submanifolds of higher codimension, the construction of the expected symplectic form on that kind of projective bundles needs be elaborated. This can be completed with the construction of the minimal coupling by Sternberg and Weinstein. To the knowledge of the author Polterovich, [31] first used the coupling form in the study of symplectic topology. It had been furthermore used in [32] (also see [33]) and [3].

To state our results, we need to review several notions. Firstly, for the conveniences of the readers, we recall the definition of the π_1 -sensitive Hofer-Zehnder capacity c_{HZ}° . It was introduced by the author [15, 16] (denoted by $\tilde{C}_{HZ}$), and Schwarz [36] independently. Recall that in [9], a smooth real function H on a symplectic manifold (M, ω) is called *admissible* if there exist an nonempty open subset U and a compact subset $K \subset M \setminus \partial M$ such that

- (a) $H|_U = 0$ and $H|_{M \setminus K} = \max H$;
- (b) $0 \leq H \leq \max H$;
- (c) $\dot{x} = X_H(x)$ has no nonconstant fast periodic solutions.

Here X_H is defined by $i_{X_H}\omega = dH$, and “fast” means “of period less than 1”. Denote by $\mathcal{H}_{ad}(M, \omega)$ the set of admissible Hamiltonians on (M, ω) . The Hofer-Zehnder symplectic capacity of (M, ω) is defined by $c_{HZ}(M, \omega) = \sup \{ \max H \mid H \in \mathcal{H}_{ad}(M, \omega) \}$. If the condition (c) in the definition of the admissibility is replaced by the condition $(c)^\circ$, $\dot{x} = X_H(x)$ has no nonconstant fast and contractible periodic solutions, the corresponding function H is said to be 0-admissible. Let $\mathcal{H}_{ad}^\circ(M, \omega)$ be the set of 0-admissible Hamiltonians on (M, ω) . Then the π_1 -sensitive Hofer-Zehnder capacity of (M, ω) is defined by

$$(1.1) \quad c_{HZ}^\circ(M, \omega) = \sup \{ \max H \mid H \in \mathcal{H}_{ad}^\circ(M, \omega) \}.$$

It always holds that $\mathcal{W}_G \leq c_{HZ}(M, \omega) \leq c_{HZ}^\circ(M, \omega)$ for them and the Gromov symplectic width $\mathcal{W}_G$.

Recall that a *symplectic fibration* $\Pi : M \rightarrow B$ with symplectic fibre (F, σ) is a fibration whose structure group is a subgroup of $\text{Symp}(F, \sigma)$. In this case, for any local trivialization $\Phi : \Pi^{-1}(U) \rightarrow U \times F$ and any $b \in U$, there exists a natural symplectic form $\sigma_b = \Phi_b^* \sigma$ on the fiber F_b which is independent of the choice of the local trivialization Φ , where $\Phi_b : F_b \rightarrow F$ is the restriction of Φ to F_b followed by the projection onto F . A symplectic form ω on M is said to be *compatible* with the symplectic fibration Π if $\sigma_b = \iota_b^* \omega$ for each inclusion $\iota_b : F_b \hookrightarrow M$ of the fibre, that is, each fibre (F_b, σ_b) is a symplectic submanifold of (M, ω) .

Let $\pi : (E, \bar{\omega}) \rightarrow B$ be a $2n$ -dimensional symplectic vector bundle over a compact symplectic manifold (B, β) (with or without boundary). It may be naturally viewed as a symplectic fibration with symplectic fibre $(\mathbb{R}^{2n}, \omega_{std})$, and hence each fibre E_b carries a natural symplectic structure $(\omega_{std})_b$, (cf. Section 3 for details). Throughout this paper, we use ω_{std} (or $\omega_{std}^{(n)}$ if necessary) to denote the standard symplectic form on $\mathbb{R}^{2n}$. With a $\bar{\omega}$ -compatible complex structure $J_E \in \mathcal{J}(E, \bar{\omega})$, one gets a Hermitian structure $(\bar{\omega}, J_E, g_{J_E})$ on E . Denote by $\mathcal{F} : U(E) \rightarrow B$ the bundle of unitary frames of E . It is a principal $U(n)$ -bundle, and E is an associated bundle, $E = U(E) \times_{U(n)} \mathbb{C}^n$, (see (3.18) for an explicit identification). Hereafter, the unitary group $U(n)$ acts on $\mathbb{C}^n$ via

$$(1.2) \quad U \cdot (z_1, \dots, z_n) = (z_1, \dots, z_n)U \quad \forall U = X + iY \in U(n).$$

This action is Hamiltonian with respect to ω_{std} , and has the moment map

$$(1.3) \quad \mu_{U(n)} : \mathbb{C}^n \rightarrow \mathfrak{u}(n), \quad z = (z_1, \dots, z_n) \mapsto \frac{i}{2} z^t \bar{z}$$

after identifying the Lie algebra $\mathfrak{u}(n) = T_{I_n}U(n)$ with its dual $\mathfrak{u}(n)^*$ via the inner product $(X, Y) = \text{Tr}(\bar{X}^t Y)$. Denote by

$$(1.4) \quad D_\varepsilon(E) = U(E) \times_{U(n)} B^{2n}(\varepsilon)$$

the open disk bundle of radius $\varepsilon > 0$. Here $B^{2n}(\varepsilon) = \{\mathbf{z} \in \mathbb{C}^n \mid |\mathbf{z}| < \varepsilon\}$. Let $\mathcal{A}(U(E))$ be the affine space of all connection ($\mathfrak{u}(n)$ -value) 1-forms on $U(E)$. By the construction due to Sternberg and Weinstein, (cf. Theorem 3.2(8°)), for each $A \in \mathcal{A}(U(E))$ there are $0 < \varepsilon_0 = \varepsilon_0(\mathcal{F}, A) \leq 1$ and a canonical symplectic form $\bar{\omega}_A$ in $D_{\varepsilon_0}(E)$ such that

$$(1.5) \quad \bar{\omega}_A|_{D_{\varepsilon_0}(E)_b} = (\omega_{\text{std}})_b|_{D_{\varepsilon_0}(E)_b} \quad \forall b \in B,$$

and that the symplectic normal bundle of the zero section 0_E in $(D_{\varepsilon_0}(E), \bar{\omega}_A)$ is $(E, \bar{\omega})$. For each $t > 0$ let

$$(1.6) \quad \bar{\omega}_A^t := \pi^* \beta + t(\bar{\omega}_A - \pi^* \beta).$$

It restricts to $t(\omega_{\text{std}})_b$ on each fibre $D_{\varepsilon_0}(E)_b$, and for every $0 < \varepsilon < \varepsilon_0$ there is $t_0 = t_0(A, \varepsilon) > 0$ such that $\bar{\omega}_A^t$ is also symplectic in $D_\varepsilon(E)$ for each $0 < t < t_0(A, \varepsilon)$, the reader may refer to Theorems 3.3(v). The pair $(D_\varepsilon(E), \bar{\omega}_A^t)$ is our *symplectic tubular neighborhood* of B . Our main result is the following theorem.

Theorem 1.3. *Let B be any closed symplectic submanifold in any symplectic manifold (M, ω) and let $\pi : (E, \bar{\omega}) \rightarrow B$ be the symplectic normal bundle of B in (M, ω) . For a given $J_E \in \mathcal{J}(E, \bar{\omega})$, let $\mathcal{F} : U(E) \rightarrow B$ be the corresponding bundle of unitary frames. Then for a connection 1-form $A \in \mathcal{A}(U(E))$ and $\bar{\omega}_A^t$ in (1.6) with $\beta = \omega|_B$, it holds that*

$$(1.7) \quad c_{HZ}(D_\varepsilon(E), \bar{\omega}_A^t) \leq c_{HZ}^\circ(D_\varepsilon(E), \bar{\omega}_A^t) \leq \pi t \varepsilon^2$$

for any $0 < \varepsilon < \varepsilon_0(\mathcal{F}, A)$ and $0 < t < t_0(\varepsilon, A)$. Furthermore

$$(1.8) \quad \mathcal{W}_G(D_\varepsilon(E), \bar{\omega}_A^t) = c_{HZ}(D_\varepsilon(E), \bar{\omega}_A^t) = c_{HZ}^\circ(D_\varepsilon(E), \bar{\omega}_A^t) = \pi t \varepsilon^2$$

for sufficiently small $\varepsilon > 0$ and $t > 0$. So for any $\epsilon > 0$ there exists an open neighborhood W of B in M such that

$$(1.9) \quad \mathcal{W}_G(W, \omega) = c_{HZ}(W, \omega) = c_{HZ}^\circ(W, \omega) < \epsilon.$$

From the proof of Theorem 1.3, it is easily seen that for the above $(U_R, \omega|_B + d(g_E(v, v)\alpha))$ there exist $0 < \epsilon \ll \varepsilon$ and a symplectic embedding from $(D_\epsilon(E), \bar{\omega}_A^t)$ into $(U_R, \omega|_B + d(g_E(v, v)\alpha))$ which maps the zero section 0_E onto 0_E . Conversely, there exist $0 < r \ll R$ and a symplectic embedding from $(U_r, \omega|_B + d(g_E(v, v)\alpha))$ into $(D_\varepsilon(E), \bar{\omega}_A^t)$ mapping the zero section 0_E onto 0_E .

It is well known that the Hofer-Zehnder capacity and pseudo symplectic capacity are closely related to the famous Weinstein conjecture in [40], (cf. [9, 23]). Every compact smooth hypersurface $\mathcal{S}$ in a symplectic manifold (M, ω) determines a distinguished line bundle $T\mathcal{S} \supset \mathcal{L}_\mathcal{S} \rightarrow \mathcal{S}$ whose fiber at $x \in \mathcal{S}$ is given by $T_x\mathcal{S} \cap (T_x\mathcal{S})^\omega$. A closed characteristic of $\mathcal{S}$ is an embedded circle $P \subset \mathcal{S}$ satisfying $TP = \mathcal{L}_\mathcal{S}|_P$. The hypersurface $\mathcal{S}$ is said to be of *contact type* if there exists a Liouville vector field X (i.e., $L_X\omega = \omega$) in some neighborhood of it which is transversal to $\mathcal{S}$ everywhere. Weinstein [40] conjectured that *every hypersurface $\mathcal{S}$ of contact type in symplectic manifolds carries a closed characteristic*. After Viterbo [39] first proved it in the standard Euclidean symplectic space this conjecture was proved in many symplectic manifolds, (cf. [5, 23, 35] and the references therein for a detailed description of the progress on this question). As a direct consequence of (1.9), we get the following corollary.

Corollary 1.4. *Let W be a neighborhood of B as in (1.9). Then for every smooth function $H : M \rightarrow \mathbb{R}$ supported in W and with $\max H - \min H > c_{HZ}^\circ(W)$, its Hamiltonian flow has a nontrivial contractible periodic orbit of period less than or equal to one. Moreover, for a compact hypersurface $\mathcal{S}$ contained in W and every thickening of $\mathcal{S}$ in W , $\psi : \mathcal{S} \times (-1, 1) \rightarrow W$ there is a closed characteristic on $\mathcal{S}_t := \psi(\mathcal{S} \times t)$ for almost every $t \in (-1, 1)$. In particular, the Weinstein conjecture holds near a closed symplectic submanifold B in any symplectic manifold (M, ω) .*

So Corollary 1.4 generalizes the corresponding results in [2, 6, 11, 23, 25]. The proof from (1.9) to Corollary 1.4 is standard, see [10, 26, 38]. Another direct consequence of (1.9) is the following corollary.

Corollary 1.5. *Let (N, σ) be any closed symplectic manifold. Then there is an open neighborhood U of the zero section in the twisted cotangent bundle $(T^*N, \omega_{\text{can}} + \pi^*\sigma)$ such that $c_{HZ}^\circ(U, \omega_{\text{can}} + \pi^*\sigma) < \infty$.*

This implies the existence of contractible periodic orbits of a charge on the symplectic manifold N subject to the magnetic field σ on almost every sufficiently small energy level. A more general result was recently obtained in [35] by a different method. The reader may also find some related interesting results in [11]. Equation (1.9) also implies some nonsqueezing phenomenon in symplectic geometry which was first discovered by Gromov in his celebrated paper [7]. For example, it implies that a given standard symplectic ball $(B^{2n}(r), \omega_{\text{std}})$ can not be symplectically embedded in a small neighborhood of a closed symplectic submanifold in any symplectic manifold of dimension $2n$.

The organization of the paper is as follows. In the next section we first review the minimal coupling procedure by Sternberg and Weinstein following [37, Appendix], and then prove the main result Theorem 2.5 therein. In Section 3, we shall construct the symplectic forms on the total space of the projectivized bundle of the sum of the symplectic normal bundle and the trivial line bundle, and study their properties. Theorems 3.2, 3.3 summarize our main results in that section. The main result Theorem 1.3 will be proved in Section 4 after main results Theorems 4.4-4.5 in that section.

2. MINIMAL COUPLING AND SYMPLECTIC REDUCTION

In this section, we first briefly review how to use the minimal coupling form procedure of Sternberg and Weinstein to construct the symplectic structures on the associated bundle, and then point out some properties of such symplectic structures. Those properties are needed in our arguments and are easily proved. Our main reference is [37, Appendix].

Let G be a compact Lie group with Lie algebra $\mathfrak{g}$, and let $\langle \cdot, \cdot \rangle$ denote the pairing between the dual Lie algebra $\mathfrak{g}^*$ and $\mathfrak{g}$. For a Hamiltonian G -space (M, ω) , let $\mu_G : M \rightarrow \mathfrak{g}^*$ denote the Ad^* -equivariant moment map. The famous Marsden-Weinstein reduction theorem is shown as follows.

Theorem 2.1. *Suppose that 0 is a regular value of μ_G and that the group G acts freely and properly on $\mu_G^{-1}(0)$. Then $\mu_G^{-1}(0)$ is a coisotropic submanifold in (M, ω) and the corresponding isotropic foliation is given by the orbits of G . Moreover, there exists a unique symplectic form ω_G on the Marsden-Weinstein quotient $M//G := \mu_G^{-1}(0)/G$ such that $q_G^* \omega_G = \omega|_{\mu_G^{-1}(0)}$, where $q_G : \mu_G^{-1}(0) \rightarrow M//G$ is the quotient projection.*

A symplectic submanifold $N \subset M$ is called a *Hamiltonian G -subspace* of (M, ω) if $g \cdot N = \{g \cdot x \mid x \in N\} \subset N$ for each $g \in G$. Clearly, for a Hamiltonian G -subspace $N \subset M$ of (M, ω) , the moment map of the G -action on (M, ω) restricts to that of the induced G -action on $(N, \omega|_N)$. By Theorem 2.1, one easily gets the following proposition.

Proposition 2.2. *For a Hamiltonian G -subspace N of (M, ω) , if 0 is also a regular value of $\mu_G|_N$ and G also acts freely and properly on $(\mu_G|_N)^{-1}(0)$, then the restriction of ω_G to $N//G = (\mu_G|_N)^{-1}(0)/G$ is exactly the unique symplectic structure from symplectic reduction of the Hamiltonian G -subspace $(N, \omega|_N)$.*

Now let $\pi_P : P \rightarrow B$ be a principal G -bundle over a compact symplectic manifold (B, β) , and let $\pi_2 : P \times \mathfrak{g}^* \rightarrow \mathfrak{g}^*$ be the natural projection to the second factor. Every connection 1-form $A \in \mathcal{A}(P)$ yields a corresponding *minimal coupling form* on $P \times \mathfrak{g}^*$ defined by

$$(2.1) \quad \delta_A = \pi_P^* \beta - d\langle \pi_2, A \rangle.$$

By the transformation properties of connections, $\langle \pi_2, A \rangle$, and hence δ_A , is G -invariant under the diagonal action

$$(2.2) \quad g \cdot (p, \zeta) = (g^{-1} \cdot p, \text{Ad}(g)^* \zeta).$$

Moreover, the injection $\iota : P \rightarrow P \times \mathfrak{g}^*$ given by $\iota(p) = (p, 0)$ is G -equivariant and $\iota^* \delta_A = \pi_P^* \beta$. It is also easily checked that δ_A is nondegenerate at all points of $\iota(P)$.

Theorem 2.3. *Under the above assumptions, there exists a neighborhood $\mathcal{W}$ of zero in $\mathfrak{g}^*$ (which depends on A and on the principal bundle π_P , and can also be required to be invariant under the coadjoint action of G) such that the following hold.*

- (i) *The minimal coupling form δ_A restricts to a symplectic form on $P \times \mathcal{W}$.*
- (ii) *The action of G on $P \times \mathfrak{g}^*$ given by (2.2) is Hamiltonian with respect to δ_A on $P \times \mathcal{W}$ and has the moment map, $-\pi_2 : P \times \mathfrak{g}^* \rightarrow \mathfrak{g}^*$.*
- (iii) *For two different connection 1-forms A_1 and A_2 on P , let $\mathcal{W}_1$ (resp., $\mathcal{W}_2$) be the corresponding neighborhood of zero in $\mathfrak{g}^*$ such that the minimal coupling form δ_{A_1} (resp., δ_{A_2}) is symplectic on $P \times \mathcal{W}_1$ (resp., on $P \times \mathcal{W}_2$). Then there are smaller neighborhoods of zero in $\mathfrak{g}^*$, $\mathcal{W}_1^* \subset \mathcal{W}_1$ and $\mathcal{W}_2^* \subset \mathcal{W}_2$ such that there*

exists a symplectomorphism from $(P \times \mathcal{W}_1^*, \delta_{A_1})$ onto $(P \times \mathcal{W}_2^*, \delta_{A_2})$ that not only commutes with the action of G but also restricts to the identity on $P \times \{0\}$.

Theorem 2.4. *Under the assumptions of Theorem 2.3, furthermore assume that (F, σ) is a Hamiltonian G -space with moment map $\mu_G^F : F \rightarrow \mathfrak{g}^*$ satisfying*

$$(2.3) \quad \mu_G^F(F) \subset \mathcal{W}.$$

Then the diagonal action of G on $W := (P \times \mathcal{W}) \times F$ is Hamiltonian and the corresponding moment map is given by

$$(2.4) \quad \mu_G^W : W \rightarrow \mathfrak{g}^*, (p, g^*, f) \mapsto \mu_G^F(f) - g^*.$$

Moreover, there exists a symplectic form ω_A on the total space of the associated fibre bundle $\pi_F : M := P \times_G F \rightarrow B$ such that the map $(F, \sigma) \hookrightarrow (M, \omega_A)$ is a symplectic embedding, that is, $\omega_A|_{M_b} = \sigma_b$ for any $b \in B$, where σ_b is the symplectic form on M_b obtained from the symplectic fibration $M \rightarrow B$ with symplectic fibre (F, σ) . Consequently, each fibre is a symplectic submanifold.

Indeed, it is easy to check that 0 is a regular value of μ_G^W , and that

$$(2.5) \quad \hat{\Upsilon} : P \times F \rightarrow (\mu_G^W)^{-1}(0), (p, f) \mapsto (p, \mu_G^F(f), f)$$

is a G -equivariant diffeomorphism. Moreover, G acts freely on $(\mu_G^W)^{-1}(0)$. The Marsden-Weinstein reduction procedure yields a unique symplectic form ω'_A on the quotient $(\mu_G^W)^{-1}(0)/G$ whose pullback under the quotient projection $\Pi_W : (\mu_G^W)^{-1}(0) \rightarrow (\mu_G^W)^{-1}(0)/G$ is equal to the restriction of $\delta_A \oplus \sigma$ to $(\mu_G^W)^{-1}(0)$. Let $\Upsilon : P \times_G F \rightarrow (\mu_G^W)^{-1}(0)/G$ be the diffeomorphism induced by $\hat{\Upsilon}$. Then the symplectic form $\omega_A = \Upsilon^* \omega'_A$ satisfies the desired requirements. *Note that shrinking $\mathcal{W}$ while preserving (2.3), one obtains the same symplectic form ω_A on $P \times_G F$. The following theorem summarizes some related properties of the above constructions. Their proofs are easy, (cf. [22]).*

Theorem 2.5. *Under the assumptions of Theorem 2.4, the following properties hold.*

- (i) *Let $(F^\sharp, \sigma^\sharp)$ be another Hamiltonian G -space of dimension $\dim F$ with moment map satisfying (2.3). If there exists a symplectic embedding $\varphi : (F^\sharp, \sigma^\sharp) \rightarrow (F, \sigma)$ which commutes with the Hamiltonian actions of G on $(F^\sharp, \sigma^\sharp)$ and (F, σ) , that*

is, $g \cdot \varphi(x) = \varphi(g \cdot x)$ for all $g \in G$ and $x \in F^\sharp$, then the bundle embedding $\varphi_P : M^\sharp := P \times_G F^\sharp \rightarrow M$ induced by φ is a symplectic embedding from $(M^\sharp, \omega_A^\sharp)$ to (M, ω_A) , where $\omega_A^\sharp$ is the symplectic form on $M^\sharp$ constructed as above. Furthermore, if F_0 is a Hamiltonian G -subspace of (F, σ) , then $P \times_G F_0$ is a symplectic submanifold in (M, ω_A) .

- (ii) If F is a vector space and $\mu_G^F(0) = 0$, then the zero section $Z_0 := P \times_G \{0\} \subset M$ is a symplectic submanifold. More precisely, $\omega_A|_{Z_0} = \pi_F^* \beta|_{Z_0}$. Consequently, Z_0 is a symplectic submanifold in (M, ω_A) and the symplectic normal space $(T_{(b,0)} Z_0)^{\omega_A}$ at any point $(b, 0) \in Z_0$ is exactly the symplectic vector space $(M_b, \sigma_b(0))$ (because $T_{(b,0)} M = T_{(b,0)} Z_0 \oplus T_0 M_b = T_{(b,0)} Z_0 \oplus M_b$).
- (iii) For any compact symplectic submanifold $B^\circ \subset B$, (since the connection form A can always restrict to a connection form on the restriction principal bundle $P^\circ := P|_{B^\circ}$), the corresponding minimal coupling form $\delta_A^\circ = \pi_{P^\circ}^* \beta - d\langle \pi_2, A|_{P^\circ} \rangle$ on $P^\circ \times \mathfrak{g}^*$ is equal to the restriction of the coupling form δ_A on $P \times \mathfrak{g}^*$ to $P^\circ \times \mathfrak{g}^*$. By shrinking $\mathcal{W}$, assume that δ_A (resp., δ_A°) is nondegenerate on $P \times \mathcal{W}$ (resp., $P^\circ \times \mathcal{W}$). Then $M^\circ := (P|_{B^\circ}) \times_G F$ is also a symplectic submanifold in (M, ω_A) and $\omega_A|_{M^\circ}$ is exactly equal to the symplectic form constructed in the above method from the restriction of the connection form A on the principal G subbundle $P^\circ \rightarrow B^\circ$.
- (iv) In the trivial principal bundle $P = B \times G$, there exists a canonical flat connection defined by $\mathcal{H}_u^{cf} = \text{Ker}(\Pi_{2*}) : T_u(B \times G) \rightarrow T_g G$, where $\Pi_2 : B \times G \rightarrow G$ is the projection on the second factor. The corresponding connection form is given by $A_{\text{can}} := \Pi_2^* \theta$. Here θ is the canonical left invariant $\mathfrak{g}$ -valued 1-form defined by $\theta(a)(\tilde{X}(a)) = X \in \mathfrak{g}$ for $a \in G$, $X \in \mathfrak{g}$, where $\tilde{X}$ is the unique left invariant vector field on G which has value X at e . Then the symplectic form $\omega_{A_{\text{can}}}$ on $P \times_G F = B \times F$ is equal to $\beta \oplus \sigma$. Here the condition (2.3), of course, has been assumed, but the present $\mathcal{W}$ depends merely on G itself.
- (v) Let A_1 and A_2 be two connection forms on P . Suppose that $\mu_F^G(F)$ is contained in the intersection of the open subsets $\mathcal{W}_1^*$ and $\mathcal{W}_2^*$ in Theorem 2.3(iii). Then there exists a bundle isomorphism $\Phi : P \times_G F \rightarrow P \times_G F$ which sends ω_{A_1} to ω_{A_2} , i.e., $\Phi^* \omega_{A_2} = \omega_{A_1}$.

Remark 2.6. For a Hamiltonian G -space (F, σ) with moment map $\mu_G^F : F \rightarrow \mathfrak{g}^*$, there always exists $\varepsilon_0 = \varepsilon_0(\mathcal{W}, F, \sigma, G)$ such that $\varepsilon^2 \mu_G^F(F) \subset \mathcal{W}$ for any $\varepsilon \in (0, \varepsilon_0]$. Since the G -action is also Hamiltonian with respect to $\varepsilon^2 \sigma$ and the corresponding moment $\mu_G^\varepsilon = \varepsilon^2 \mu_G^F : F \rightarrow \mathfrak{g}^*$, one can always obtain a family of deformedly equivalent symplectic forms $\{\omega_{A\varepsilon} \mid 0 < \varepsilon \leq \varepsilon_0\}$ on $P \times_G F$. Here the reason that we use $\varepsilon^2 \sigma$ (and thus $\varepsilon^2 \mu_G^F$), instead of $\varepsilon \sigma$ (and $\varepsilon \mu_G^F$), will be seen in next section.

3. SYMPLECTIC FORMS ON PROJECTIVE BUNDLES

In this section, we shall construct two families of symplectic forms on the disk bundle and projective bundle, and give their properties. Firstly, a $2n$ -dimensional symplectic vector bundle $\pi : (E, \bar{\omega}) \rightarrow B$ may be naturally viewed as a symplectic fibration with symplectic fibre $(\mathbb{R}^{2n}, \omega_{\text{std}})$. Let $\bar{\omega}_{\text{std}}$ denote the standard skew-symmetric bilinear map on $\mathbb{R}^{2n}$. Taking any $J_E \in \mathcal{J}(E, \bar{\omega})$ and setting $g_{J_E} : E \times E \rightarrow \mathbb{R}$, $g_{J_E}(u, v) = \bar{\omega}(u, J_E v)$, one gets a Hermitian structure $(\bar{\omega}, J_E, g_{J_E})$ on E , (cf. [29]). Then one can choose an open cover $\{U_\alpha\}_{\alpha \in \Lambda}$ of B such that for each $\alpha \in \Lambda$, there exists a unitary trivialization

$$(3.1) \quad U_\alpha \times \mathbb{R}^{2n} \rightarrow E|_{U_\alpha} : (b, v) \mapsto \Phi_\alpha(b)v$$

satisfying $\Phi_\alpha^* J_E = J_{\text{std}}$, $\Phi_\alpha^* \bar{\omega} = \bar{\omega}_{\text{std}}$, and $\Phi_\alpha^* g_{J_E} = g_{\text{std}}$. Here g_{std} and J_{std} are the standard inner product and complex structure on $\mathbb{R}^{2n}$, respectively. As a symplectic fibration $E \rightarrow B$, each fibre E_b carries a natural symplectic structure

$$(3.2) \quad (\omega_{\text{std}})_b := (\Phi_\alpha(b)^{-1})^* \omega_{\text{std}} \quad (\text{if } b \in U_\alpha)$$

to satisfy $(\omega_{\text{std}})_b|_{T_0 E_b} = \bar{\omega}_b$.

The Lie algebra $\mathfrak{u}(n) = \{X \in M_n(\mathbb{C}) \mid \bar{X}^t = -X\}$ of $U(n)$ carries an invariant (real) inner product defined by $(X, Y) = \text{Tr}(\bar{X}^t Y)$. By Riesz theorem, for each $f \in \mathfrak{u}(n)^*$, there exists a unique $\zeta_f \in \mathfrak{u}(n)$ such that $\langle f, \xi \rangle = (\xi, \zeta_f)$ for any $\xi \in \mathfrak{u}(n)$. Since $\zeta_{Ad_g^* f} = Ad_{g^{-1}} \zeta_f$ for any $f \in \mathfrak{u}(n)$, and

$$(3.3) \quad \mathfrak{u}(n)^* \rightarrow \mathfrak{u}(n), f \mapsto \zeta_f$$

is a real vector space isomorphism, we may identify $\mathfrak{u}(n)^*$ with $\mathfrak{u}(n)$ and Ad_g^* with $Ad_{g^{-1}}$. It is under such identifications that the moment map of the action of $U(n)$ on $(\mathbb{C}^n, \omega_{\text{std}})$ in (1.2) is given by (1.3).

Let J_{FS} be the standard complex structure on the n -dimensional complex projective space $\mathbb{C}P^n = (\mathbb{C}^{n+1} - \{0\})/\mathbb{C}^*$. The standard action of $U(n+1)$ on $\mathbb{C}^{n+1}$ as in (1.2) induces a natural one on $\mathbb{C}P^n$:

$$(3.4) \quad U \cdot [z_0, \dots, z_n] = [(z_0, \dots, z_n)U]$$

for any $[z_0, \dots, z_n] \in \mathbb{C}P^n$ and $U \in U(n+1)$. Let ω_{FS} be the unique $U(n+1)$ -invariant Kähler form on $\mathbb{C}P^n$ associated with the *Fubini-Study metric* which has integration π on $\mathbb{C}P^1 \subset \mathbb{C}P^n$. The action in (3.4) is Hamiltonian with respect to ω_{FS} , and in homogeneous coordinates $[z_0, \dots, z_n]$, the corresponding moment map $\mu'_{U(n+1)} : \mathbb{C}P^n \rightarrow \mathfrak{u}(n+1)^*$ is given by

$$(3.5) \quad \langle \mu'_{U(n+1)}([z]), \zeta \rangle = \frac{i}{2} \frac{\sum_{j,k} \zeta_{jk} \bar{z}_j z_k}{\sum_j |z_j|^2}.$$

Identifying $\mathfrak{u}(n+1)^*$ with $\mathfrak{u}(n+1)$ via the isomorphism as in (3.3), the moment map $\mu'_{U(n+1)} : \mathbb{C}P^{n+1} \rightarrow \mathfrak{u}(n+1)$ is written as

$$(3.6) \quad \mu'_{U(n+1)}([z]) = \frac{i}{2} \frac{z^t \bar{z}}{\sum_j |z_j|^2} = \left(-\frac{1}{2} \frac{(\bar{z}_j z_k - \bar{z}_k z_j)}{\sum_j |z_j|^2} \right).$$

Consider the Lie group inclusion homomorphism

$$(3.7) \quad \varphi : U(n) \rightarrow U(n+1), \quad U \mapsto \begin{pmatrix} U & 0 \\ 0 & 1 \end{pmatrix},$$

we easily get the following proposition.

Proposition 3.1. *The action of $U(n)$ on $\mathbb{C}P^n$ via*

$$(3.8) \quad U \cdot [z_0, \dots, z_n] = [(z_0, \dots, z_{n-1})U, z_n]$$

is Hamiltonian and the moment map $\mu''_{U(n)} : \mathbb{C}P^n \rightarrow \mathfrak{u}(n)$ is given by

$$(3.9) \quad \mu''_{U(n)} : \mathbb{C}P^n \rightarrow \mathfrak{u}(n), \quad z \mapsto \frac{i}{2} \frac{Z^t \bar{Z}}{\sum_{l=0}^n |z_l|^2}.$$

Here $Z = (z_0, \dots, z_{n-1})$ and $\mathfrak{u}(n)^$ has been identified with $\mathfrak{u}(n)$ via (3.3).*

Using the action in (3.8), one can form a $\mathbb{C}P^n$ -bundle

$$(3.10) \quad \mathcal{P} : U(E) \times_{U(n)} \mathbb{C}P^n \rightarrow B,$$

which is exactly the projective bundle $P(E \oplus \mathbb{C})$. Denote by

$$(3.11) \quad Z_0 := P(\{0\} \oplus \mathbb{C}) \quad \text{and} \quad Z_\infty := P(E \oplus \{0\})$$

the zero section and divisor at infinity respectively. The symplectic embedding

$$(3.12) \quad \varphi : (B^{2n}(1), \omega_{\text{std}}) \rightarrow (\mathbb{C}P^n, \omega_{\text{FS}}), \quad \mathbf{z} \mapsto [\mathbf{z}, \sqrt{1 - |\mathbf{z}|^2}]$$

satisfies

$$(3.13) \quad \varphi(U \cdot \mathbf{z}) = [U \cdot \mathbf{z}, \sqrt{1 - |\mathbf{z}|^2}] = U \cdot \varphi(\mathbf{z}),$$

and hence induces an embedding

$$(3.14) \quad \varphi_{\mathcal{P}} : U(E) \times_{U(n)} B^{2n}(1) \rightarrow U(E) \times_{U(n)} \mathbb{C}P^n, \quad [f, \mathbf{z}] \mapsto [f, \varphi(\mathbf{z})]$$

that maps the zero sections $0_E \subset D_1(E)$ onto $Z_0 \subset P(E \oplus \mathbb{C})$. Here $D_1(E)$ is defined by (1.4), i.e., $D_1(E) = U(E) \times_{U(n)} B^{2n}(1)$.

Theorem 3.2. *For each given connection 1-form A on $\mathcal{F} : U(E) \rightarrow B$, there exist a small $\varepsilon_0 = \varepsilon_0(\mathcal{F}, A) > 0$ and two smooth families of (compatible) symplectic forms $\{\omega_{A\varepsilon} \mid 0 < \varepsilon < \varepsilon_0\}$ ¹ on $D_1(E)$, and $\{\Omega_{A\varepsilon} \mid 0 < \varepsilon < \varepsilon_0\}$ on $P(E \oplus \mathbb{C})$ such that the following properties hold:*

- (1°) *The maps $(B^{2n}(1), \varepsilon^2 \omega_{\text{std}}) \hookrightarrow (D_1(E), \omega_{A\varepsilon})$ and $(\mathbb{C}P^n, \varepsilon^2 \omega_{\text{FS}}) \hookrightarrow (P(E \oplus \mathbb{C}), \Omega_{A\varepsilon})$ are all symplectic embeddings.*
- (2°) *The map $\varphi_{\mathcal{P}}$ in (3.14) is a symplectic embedding from $(D_1(E), \omega_{A\varepsilon})$ to $(P(E \oplus \mathbb{C}), \Omega_{A\varepsilon})$.*
- (3°) *The zero section $0_E \subset E$ is a symplectic submanifold in $(D_1(E), \omega_{A\varepsilon})$ with symplectic normal bundle $(E, \varepsilon^2 \bar{\omega}) \rightarrow B$. More precisely, for any $b \in B$,*

$$(3.15) \quad \omega_{A\varepsilon}|_{D_1(E)_b} = \varepsilon^2 (\omega_{\text{std}})_b \quad \text{and} \quad \Omega_{A\varepsilon}|_{P(E \oplus \mathbb{C})_b} = \varepsilon^2 (\omega_{\text{FS}})_b,$$

where $(\omega_{\text{std}})_b$ is defined by (3.2), and $(\omega_{\text{FS}})_b$ comes from $P(E \oplus \mathbb{C})$ being a symplectic fibration with symplectic fibre $(\mathbb{C}P^n, \omega_{\text{FS}})$. So the symplectic forms $\omega_{A\varepsilon}$ and $\Omega_{A\varepsilon}$ are compatible with the symplectic fibrations.

- (4°) *The zero section Z_0 and the divisor Z_∞ at infinity are symplectic submanifolds in $(P(E \oplus \mathbb{C}), \Omega_{A\varepsilon})$.*

¹Hereafter the subscript $A\varepsilon$ does not mean to multiply A by ε !

- (5°) If F_0 is a Hamiltonian G -subspace of $(B^{2n}(1), \omega_{\text{std}})$ (resp., $(\mathbb{C}P^n, \omega_{\text{FS}})$), then $U(E) \times_{U(n)} F_0$ is a symplectic submanifold in $(D_1(E), \omega_{A_\varepsilon})$ (resp., $(P(E \oplus \mathbb{C}), \Omega_{A_\varepsilon})$).
- (6°) For any compact symplectic submanifold $B^\circ \subset B$, let $U(E)^\circ = U(E)|_{B^\circ}$ and $\{\omega_{A_\varepsilon}^\circ \mid 0 < \varepsilon < \varepsilon_0^\circ\}$ (resp., $\{\Omega_{A_\varepsilon}^\circ \mid 0 < \varepsilon < \varepsilon_0^\circ\}$) be the corresponding family of symplectic forms on $D_1(E)^\circ := U(E)^\circ \times_{U(n)} B^{2n}(1)$ (resp., $P(E \oplus \mathbb{C})^\circ := U(E)^\circ \times_{U(n)} \mathbb{C}P^n$) obtained by the restriction connection form $A|_{U(E)^\circ}$. Then $\omega_{A_\varepsilon}^\circ$ (resp., $\Omega_{A_\varepsilon}^\circ$) is equal to the restriction of ω_{A_ε} (resp., Ω_{A_ε}) to $D_1(E)^\circ := U(E)^\circ \times_{U(n)} B^{2n}(1)$ (resp., $P(E \oplus \mathbb{C})^\circ := U(E)^\circ \times_{U(n)} \mathbb{C}P^n$) for each $0 < \varepsilon < \min\{\varepsilon_0^\circ, \varepsilon_0\}$.
- (7°) If P is the trivial principal bundle $P = B \times U(n)$ and A is taken as the connection form A_{can} of the canonical flat connection in P given by Theorem 2.5(iv), then for each $0 < \varepsilon < \varepsilon_0(P, A_{\text{can}})$, the symplectic form $\omega_{A_{\text{can}\varepsilon}}$ (resp., $\Omega_{A_{\text{can}\varepsilon}}$) on $P \times_{U(n)} B^{2n}(1) = B \times B^{2n}(1)$ (resp., $P \times_{U(n)} \mathbb{C}P^n = B \times \mathbb{C}P^n$) is equal to $\beta \oplus (\varepsilon^2 \omega_{\text{std}})$ (resp., $\beta \oplus (\varepsilon^2 \omega_{\text{FS}})$) for each $0 < \varepsilon < \varepsilon_0(P, A_{\text{can}})$.
- (8°) For each connection 1-form A on $U(E)$, let $\varepsilon_0 = \varepsilon_0(\mathcal{F}, A) > 0$ be as above. Then there exists a unique symplectic form $\bar{\omega}_A$ on $D_{\varepsilon_0}(E)$ such that for each $0 < \varepsilon < \varepsilon_0$,

$$(3.16) \quad \psi_\varepsilon : (D_1(E), \omega_{A_\varepsilon}) \rightarrow (D_\varepsilon(E), \bar{\omega}_A), \quad (b, v) \mapsto (b, \varepsilon v)$$

is a symplectomorphism.

- (9°) For any two different connection forms A_1 and A_2 on $\mathcal{F} : U(E) \rightarrow B$, $0 < \varepsilon \ll \min\{\varepsilon_0(\mathcal{F}, A_1), \varepsilon_0(\mathcal{F}, A_2)\}$, and $0 < \delta \leq 1$, there exist fibre bundle isomorphisms

$$(3.17) \quad \varphi_\varepsilon^\delta : D_\delta(E) \rightarrow D_\delta(E) \quad \text{and} \quad \Phi_\varepsilon : P(E \oplus \mathbb{C}) \rightarrow P(E \oplus \mathbb{C})$$

such that $(\varphi_\varepsilon^\delta)^* \omega_{A_{2\varepsilon}} = \omega_{A_{1\varepsilon}}$ and $\Phi_\varepsilon^* \Omega_{A_{2\varepsilon}} = \Omega_{A_{1\varepsilon}}$.

Proof. The proofs can be obtained by Theorem 2.5 directly. We only outline them. By the explicit equivalence between $U(E) \times_{U(n)} \mathbb{C}^n \rightarrow B$ and $E \rightarrow B$ given by

$$(3.18) \quad \Xi : [p, (z_1, \dots, z_n)] \mapsto z_1 v_1 + \dots + z_n v_n,$$

where $p = (v_1, \dots, v_n)$ is a unitary frame of E_b , for any $\varepsilon > 0$, we can write

$$(3.19) \quad D_\varepsilon(E) = \{(b, v) \in E \mid g_{J_E}(v, v) < \varepsilon^2\}.$$

For a given connection A on the principal bundle $\mathcal{F} : U(E) \rightarrow B$, let $\mathcal{W} = \mathcal{W}(A)$ be the largest open neighborhood of zero in $\mathfrak{u}(n)^*$ so that the corresponding minimal coupling

form δ_A is symplectic in $U(E) \times \mathcal{W}$. Since $Cl(B^{2n}(1))$ and $\mathbb{C}P^n$ are compact, by (3.6) and Proposition 3.1, we can choose $^2 0 < \varepsilon_0 = \varepsilon_0(A, \mathcal{F}) \leq 1$ such that

$$(3.20) \quad \varepsilon^2 \mu_{U(n)}(B^{2n}(1)) \subset \mathcal{W} \quad \text{and} \quad \varepsilon^2 \mu''_{U(n)}(\mathbb{C}P^n) \subset \mathcal{W}$$

for all $\varepsilon \in (0, \varepsilon_0)$. (For example, ones can take ε_0 to be the supremum of $\varepsilon > 0$ satisfying the inclusion relations in (3.20).) Now applying Theorem 2.4 to the cases $P = U(E)$ and $(F, \sigma) = (B^{2n}(1), \varepsilon^2 \omega_{\text{std}})$ or $(\mathbb{C}P^n, \varepsilon^2 \omega_{\text{FS}})$ we immediately get (1°).

Note that (3.13) means that the symplectic embedding φ in (3.12) commutes with the Hamiltonian actions in (1.2) and (3.8). Condition (2°) follows from Theorem 2.5(i).

The conclusion in (3°) is easily derived from Theorem 2.5(ii). It precisely says $(T_{(b,0)} 0_E)^{\omega_{A\varepsilon}} = (E_b, \varepsilon^2 \bar{\omega}_b)$ for any $b \in B$.

To see (4°), note that $\mathbb{C}P^{n-1} = \{[z_0, \dots, z_{n-1}, 0] \in \mathbb{C}P^n\} \subset \mathbb{C}P^n$ is a symplectic submanifold in $(\mathbb{C}P^n, \omega_{\text{FS}})$ that is invariant under the action in (3.8). By Theorem 2.5(i), Z_∞ is a symplectic submanifold in $(P(E \oplus \mathbb{C}), \Omega_{A\varepsilon})$. Since the symplectic embedding φ_P in (2°) maps the zero section 0_E onto $Z_0 = P(\{0\} \oplus \mathbb{C})$, Z_0 is a symplectic submanifold in $(P(E \oplus \mathbb{C}), \Omega_{A\varepsilon})$.

Theorem 3.2(5°) is a direct consequence of the final conclusion of Theorem 2.5(i). Theorem 3.2(6°), (7°) follows from Theorem 2.5(iii), (iv), respectively. Condition (8°) can easily be obtained by Theorem 2.5(i). Finally, we prove (9°). Let $\mathcal{W}_1^* \subset \mathcal{W}(A_1)$ and $\mathcal{W}_2^* \subset \mathcal{W}(A_2)$ be open neighborhoods of zero in $u(n)^*$ such that $(U(E) \times \mathcal{W}_1^*, \delta_{A_1})$ is symplectomorphic to $(U(E) \times \mathcal{W}_2^*, \delta_{A_2})$. Then for $0 < \varepsilon \ll \min\{\varepsilon_0(\mathcal{F}, A_1), \varepsilon_0(\mathcal{F}, A_2)\}$, it holds that $\varepsilon^2 \mu_{U(n)}(Cl(B^{2n}(1))) \subset \mathcal{W}^*$ and $\varepsilon^2 \mu''_{U(n)}(\mathbb{C}P^n) \subset \mathcal{W}^*$. Under this case Theorem 2.5(v) gives the desired results directly. Theorem 3.2 are proved. $\square$

Since $\omega_{A\varepsilon}$ is compatible with symplectic fibration, by Theorem 3.2(3°), we can write

$$(3.21) \quad \begin{aligned} \omega_{A\varepsilon} &= \pi^* \beta + \tau_{A\varepsilon}, \quad \tau_{A\varepsilon}|_{0_E} = 0, \\ \tau_{A\varepsilon}|_{D_1(E)_b} &= \varepsilon^2 (\omega_{\text{std}})_b \quad \forall b \in B. \end{aligned}$$

Similarly, by Theorem 3.2(4°), we easily get that $\Omega_{A\varepsilon}|_{Z_0} = \beta$ after identifying $Z_0 \equiv 0_E \equiv B$. It follows that we can also write

$$(3.22) \quad \begin{aligned} \Omega_{A\varepsilon} &= \mathcal{P}^* \beta + \Gamma_{A\varepsilon}, \quad \Gamma_{A\varepsilon}|_{Z_0} = 0, \\ \Gamma_{A\varepsilon}|_{P(E \oplus \mathbb{C})_b} &= \varepsilon^2 (\omega_{\text{FS}})_b \quad \forall b \in B. \end{aligned}$$

²Here the choice of $\varepsilon_0(A, \mathcal{F})$ shows that it is not canonical.

Note that the almost complex structure $\mathbf{J}$ on $P(E \oplus \mathbb{C})$ constructed by (4.15) is not necessarily $\Omega_{A\varepsilon}$ -tamed. However, we can show that for sufficiently small $t > 0$, the closed 2-form $\mathcal{P}^*\beta + t\Gamma_{A\varepsilon}$ is also symplectic and tame this $\mathbf{J}$ (see Lemma 4.2). Hence we are led to the following strengthened version of Theorem 3.2, whose precise statement is needed in the proof of Theorem 4.5.

Theorem 3.3. *Under the assumption of Theorem 3.2, for each $0 < \varepsilon < \varepsilon_0$, there exists a small $t_0 = t_0(A, \varepsilon) > 0$ such that for each $0 < t < t_0$, the form*

$$(3.23) \quad \omega_{A\varepsilon}^t := \pi^*\beta + t\tau_{A\varepsilon} \quad (\text{resp.}, \quad \Omega_{A\varepsilon}^t := \mathcal{P}^*\beta + t\Gamma_{A\varepsilon})$$

is a symplectic form on $D_1(E)$ (resp. $P(E \oplus \mathbb{C})$), where $\tau_{A\varepsilon}$ and $\Gamma_{A\varepsilon}$ are given by (3.21) and (3.22), respectively. Moreover, they also satisfy the following properties.

- (i) The map $(B^{2n}(1), t\varepsilon^2\omega_{\text{std}}) \hookrightarrow (D_1(E), \omega_{A\varepsilon}^t)$ and $(\mathbb{C}P^n, t\varepsilon^2\omega_{\text{FS}}) \hookrightarrow (P(E \oplus \mathbb{C}), \Omega_{A\varepsilon}^t)$ are symplectic embeddings.
- (ii) The map $\varphi_{\mathcal{P}}$ in (3.14) is a symplectic embedding from $(D_1(E), \omega_{A\varepsilon}^t)$ into $(P(E \oplus \mathbb{C}), \Omega_{A\varepsilon}^t)$.
- (iii) The zero section $0_E \subset E$ is a symplectic submanifold in $(D_1(E), \omega_{A\varepsilon}^t)$ with symplectic normal bundle $(E, t\varepsilon^2\bar{\omega}) \rightarrow B$.
- (iv) The zero section $Z_0 = P(\{0\} \oplus \mathbb{C})$ is a symplectic submanifold in $(P(E \oplus \mathbb{C}), \Omega_{A\varepsilon}^t)$.
- (v) Let the closed two-form $\bar{\omega}_A^t$ be defined by (1.6). Then for any $0 < \varepsilon < \varepsilon_0(A, \mathcal{F})$ and $0 < t < t_0(A, \varepsilon)$, $\bar{\omega}_A^t$ is symplectic in $D_\varepsilon(E)$ and

$$(3.24) \quad \psi_\varepsilon : (D_1(E), \omega_{A\varepsilon}^t) \rightarrow (D_\varepsilon(E), \bar{\omega}_A^t), \quad (b, v) \mapsto (b, \varepsilon v)$$

is also a symplectomorphism.

- (vi) For any compact symplectic submanifold $B^\circ \subset B$ of codimension zero, as in Theorem 3.2(6°), let $\omega_{A\varepsilon}^\circ$ (resp., $\Omega_{A\varepsilon}^\circ$) be the symplectic form on $D_1(E)^\circ$ (resp., $P(E \oplus \mathbb{C})^\circ$) for $0 < \varepsilon < \varepsilon_0^\circ$. As in (3.23), there exist a small $t_0^\circ(A, \varepsilon) > 0$ and two families of symplectic forms,

$$(3.25) \quad \omega_{A\varepsilon}^{\circ t} = (\pi|_{D_1(E)^\circ})^*\beta + t\tau_{A\varepsilon}^\circ \quad \text{and} \quad \Omega_{A\varepsilon}^{\circ t} = (\mathcal{P}|_{P(E \oplus \mathbb{C})^\circ})^*\beta + t\Gamma_{A\varepsilon}^\circ$$

for $0 < t < t_0^\circ(A, \varepsilon)$, where $\omega_{A\varepsilon}^\circ = (\pi|_{D_1(E)^\circ})^*\beta + \tau_{A\varepsilon}^\circ$ and $\Omega_{A\varepsilon}^\circ = (\mathcal{P}|_{P(E \oplus \mathbb{C})^\circ})^*\beta + \Gamma_{A\varepsilon}^\circ$. Then for each $0 < \varepsilon < \min\{\varepsilon_0^\circ, \varepsilon_0\}$ and $0 < t < \min\{t_0, t_0^\circ\}$, the

symplectic form $\omega_{A\varepsilon}^{\text{ot}}$ (resp., $\Omega_{A\varepsilon}^{\text{ot}}$) is equal to the restriction of $\omega_{A\varepsilon}^t$ (resp., $\Omega_{A\varepsilon}^t$) to $D_1(E)^\circ$ (resp., $P(E \oplus \mathbb{C})^\circ$).

(vii) Under the assumptions of Theorem 3.2(9°), for any $0 < t < \min\{t_0(A_1, \varepsilon), t_0(A_2, \varepsilon)\}$ and $\delta \in (0, 1]$,

$$(3.26) \quad \begin{aligned} \varphi_\varepsilon^\delta : (D_\delta(E), \omega_{A_1\varepsilon}^t) &\rightarrow (D_\delta(E), \omega_{A_2\varepsilon}^t), \\ \Phi_\varepsilon : (P(E \oplus \mathbb{C}), \Omega_{A_1\varepsilon}^t) &\rightarrow (P(E \oplus \mathbb{C}), \Omega_{A_2\varepsilon}^t) \end{aligned}$$

are all symplectomorphisms.

(viii) If $P = B \times U(n)$ and $A = A_{\text{can}}$ are as in Theorem 3.2(7°), then for any $0 < \varepsilon < \varepsilon_0(P, A_{\text{can}})$, one can take $t_0(A_{\text{can}}, \varepsilon) = \infty$ and $\bar{\omega}_{A_{\text{can}}\varepsilon}^t = \beta \oplus (t\varepsilon^2 \omega_{\text{std}})$ for each $t > 0$.

Proof. We firstly prove that $\Omega_{A\varepsilon}^t = \mathcal{P}^* \beta + t\Gamma_{A\varepsilon}$ are symplectic forms on $P(E \oplus \mathbb{C})$ for sufficiently small $t > 0$. For any $x \in P(E \oplus \mathbb{C})$ let

$$(3.27) \quad \mathcal{V}_x := \text{Ker} d\mathcal{P}(x) \subset T_x P(E \oplus \mathbb{C}).$$

Then it is equal to $T_x P(E \oplus \mathbb{C})_b$, where $b = \mathcal{P}(x)$. Since each fibre is a symplectic submanifold, the subspace of $T_x P(E \oplus \mathbb{C})$,

$$(3.28) \quad \begin{aligned} \mathcal{H}_x &:= (\mathcal{V}_x)^{\Omega_{A\varepsilon}} = \{X \in T_x P(E \oplus \mathbb{C}) \mid \Omega_{A\varepsilon}(X, Y) = 0 \ \forall Y \in \mathcal{V}_x\} \\ &= \{X \in T_x P(E \oplus \mathbb{C}) \mid \Gamma_{A\varepsilon}(X, Y) = 0 \ \forall Y \in \mathcal{V}_x\} \end{aligned}$$

is not only symplectic, but also a horizontal complement of $\mathcal{V}_x$, that is,

$$(3.29) \quad T_x P(E \oplus \mathbb{C}) = \mathcal{H}_x \oplus \mathcal{V}_x$$

is a symplectic direct sum decomposition and the projection

$$(3.30) \quad d\mathcal{P}(x) : \mathcal{H}_x \rightarrow T_b B$$

is a bijection. By Lemma 4.2, we have an almost complex structure $\mathbf{J}$ on $P(E \oplus \mathbb{C})$ and a small $\bar{t} > 0$ such that $\Omega_{A\varepsilon}^t(X, \mathbf{J}X) > 0$ for any nonzero $X \in TP(E \oplus \mathbb{C})$ and $t \in (0, \bar{t}]$. So, such $\Omega_{A\varepsilon}^t$ must be nondegenerate. Then the desired t_0 can be taken as the supremum of $\bar{t} > 0$ for which all $\Omega_{A\varepsilon}^t$ are nondegenerate for any $t \in (0, \bar{t}]$. The conclusions for $\omega_{A\varepsilon}^t$ can be proved in the same way (by constructing an almost complex structure on the compact bundle $Cl(D_1(E))$ as in (4.15)). Of course we can shrink t_0 if necessary.

Conditions (i), (iii), (iv) and (viii) are obvious. To see (ii), note that $\varphi_{\mathcal{P}}^*(\mathcal{P}^*\beta) = \pi^*(\varphi_{\mathcal{P}}^*\beta)$. So $\varphi_{\mathcal{P}}^*\Omega_{A\varepsilon} = \omega_{A\varepsilon}$ if and only if $\varphi_{\mathcal{P}}^*\Gamma_{A\varepsilon} = \tau_{A\varepsilon}$. The desired conclusion follows immediately.

To prove (v), we still use π to denote the bundle projections from $D_1(E)$ and $D_\varepsilon(E)$ to B . Then $\pi \circ \psi_\varepsilon = \pi$, and hence $d\pi \circ d\psi_\varepsilon = d\pi$. In particular, we have

$$(3.31) \quad \psi_\varepsilon^*(\pi^*\beta) = \pi^*\beta$$

For any $x \in D_1(E)$ and $y \in D_\varepsilon(E)$ let

$$(3.32) \quad \begin{aligned} \mathbf{V}_x &:= \text{Ker}(d\pi(x)), & \mathbf{H}_x &:= (\mathbf{V}_x)^{\omega_{A\varepsilon}}, \\ \mathbf{V}'_y &:= \text{Ker}(d\pi(y)), & \mathbf{H}'_y &:= (\mathbf{V}'_y)^{\bar{\omega}_A}. \end{aligned}$$

Then $T_x D_1(E) = \mathbf{H}_x \oplus \mathbf{V}_x$ and $T_y D_\varepsilon(E) = \mathbf{H}'_y \oplus \mathbf{V}'_y$. Clearly, $d\psi_\varepsilon(x)(\mathbf{V}_x) = \mathbf{V}'_{\psi_\varepsilon(x)}$. Since $\psi_\varepsilon^*\bar{\omega}_A = \omega_{A\varepsilon}$, one easily derives that $d\psi_\varepsilon(x)(\mathbf{H}_x) = \mathbf{H}'_{\psi_\varepsilon(x)}$. These imply that

$$(3.33) \quad \psi_\varepsilon^*(\bar{\omega}_A - \pi^*\beta) = \omega_{A\varepsilon} - \pi^*\beta.$$

Hence (3.31) and (3.33) together show that $\psi_\varepsilon^*\bar{\omega}_A^t = \omega_{A\varepsilon}^t$ for any t . But $\omega_{A\varepsilon}^t$ is symplectic in $D_1(E)$ for any $t \in (0, t_0)$. Hence $\bar{\omega}_A^t$ is symplectic in $D_\varepsilon(E)$ for each $0 < t < t_0(A, \varepsilon)$. The desired conclusion is proved.

Condition (vi) easily follows from Theorem 3.2(6°) and the proof of (v) above.

Finally, since $\pi \circ \varphi_\varepsilon = \pi$ and $\mathcal{P} \circ \Phi_\varepsilon = \mathcal{P}$, as in the proof of (v) one can derive (vii) from Theorem 3.2(9°) easily. $\square$

4. PROOF OF MAIN RESULT

We briefly review the definition of the pseudo symplectic capacity of the Hofer-Zehnder type introduced by the author in [23]. See [17, 19, 20, 18] for more estimates and applications.

For a connected symplectic manifold (M, ω) of dimension at least 4 and two nonzero homology classes $\alpha_0, \alpha_\infty \in H_*(M; \mathbb{Q})$, we say that a smooth function $H : M \rightarrow \mathbb{R}$ is $(\alpha_0, \alpha_\infty)$ -admissible (resp., $(\alpha_0, \alpha_\infty)^\circ$ -admissible) if there exist two compact submanifolds P and Q of M with connected smooth boundaries and of codimension zero such that the following condition groups (1), (2), (3), (4), (5), and (6) (resp., (1), (2), (3), (4), (5), and (6°)) hold:

- (1) $P \subset \text{Int}(Q)$ and $Q \subset \text{Int}(M)$;

- (2) $H|_P = 0$ and $H|_{M \setminus \text{Int}(Q)} = \max H$;
- (3) $0 \leq H \leq \max H$;
- (4) There exist chain representatives of α_0 and α_∞ , still denoted by α_0 and α_∞ , such that $\text{supp}(\alpha_0) \subset \text{Int}(P)$ and $\text{supp}(\alpha_\infty) \subset M \setminus Q$;
- (5) There are no critical values in $(0, \varepsilon) \cup (\max H - \varepsilon, \max H)$ for a small $\varepsilon = \varepsilon(H) > 0$;
- (6) The Hamiltonian system $\dot{x} = X_H(x)$ on M has no nonconstant fast periodic solutions;
- (6°) The Hamiltonian system $\dot{x} = X_H(x)$ on M has no nonconstant contractible fast periodic solutions.

Let $\mathcal{H}_{ad}(M, \omega; \alpha_0, \alpha_\infty)$ and $\mathcal{H}_{ad}^\circ(M, \omega; \alpha_0, \alpha_\infty)$ denote the sets of $(\alpha_0, \alpha_\infty)$ -admissible functions and $(\alpha_0, \alpha_\infty)^\circ$ -admissible ones, respectively. In [23], we defined

$$(4.1) \quad \begin{aligned} C_{HZ}^{(2)}(M, \omega; \alpha_0, \alpha_\infty) &:= \sup \{ \max H \mid H \in \mathcal{H}_{ad}(M, \omega; \alpha_0, \alpha_\infty) \}, \\ C_{HZ}^{(2\circ)}(M, \omega; \alpha_0, \alpha_\infty) &:= \sup \{ \max H \mid H \in \mathcal{H}_{ad}^\circ(M, \omega; \alpha_0, \alpha_\infty) \}. \end{aligned}$$

They were, respectively, called the *pseudo symplectic capacity of the Hofer-Zehnder type* and the π_1 -sensitive *pseudo symplectic capacity of the Hofer-Zehnder type*. In particular, we get a genuine symplectic capacity

$$(4.2) \quad C_{HZ}^{(2)}(M, \omega) := C_{HZ}^{(2)}(M, \omega; pt, pt)$$

and a π_1 -sensitive symplectic capacity

$$(4.3) \quad C_{HZ}^{(2\circ)}(M, \omega) := C_{HZ}^{(2\circ)}(M, \omega; pt, pt).$$

We also showed in [23, Lemma 1.4] that there exist the following relations among them, the usual Hofer-Zehnder capacity c_{HZ} and the π_1 -sensitive Hofer-Zehnder capacity c_{HZ}° :

$$(4.4) \quad C_{HZ}^{(2)}(M, \omega) = c_{HZ}(M, \omega) \quad \text{and} \quad C_{HZ}^{(2\circ)}(M, \omega) = c_{HZ}^\circ(M, \omega)$$

if a symplectic manifold (M, ω) is either closed or satisfies the condition that for each compact subset $K \subset M \setminus \partial M$, there exists a compact submanifold $W \subset M$ with connected boundary and of codimension zero such that $K \subset W$.

For a closed symplectic manifold (M, ω) and $\alpha_0, \alpha_\infty \in H_*(M; \mathbb{Q})$, let

$$(4.5) \quad \text{GW}_g(M, \omega; \alpha_0, \alpha_\infty) \in (0, +\infty]$$

be the infimum of the ω -areas $\omega(A)$ of the homology classes $A \in H_2(M; \mathbb{Z})$ for which the Gromov-Witten invariant $\Psi_{A,g,m+2}(C; \alpha_0, \alpha_\infty, \beta_1, \dots, \beta_m) \neq 0$ for some homology classes $\beta_1, \dots, \beta_m \in H_*(M; \mathbb{Q})$ and $C \in H_*(\overline{\mathcal{M}}_{g,m+2}; \mathbb{Q})$ and an integer $m \geq 1$. Here for a given class $A \in H_2(M; \mathbb{Z})$, the Gromov-Witten invariant of genus g and with $m+2$ marked points is a homomorphism

$$(4.6) \quad \Psi_{A,g,m+2} : H_*(\overline{\mathcal{M}}_{g,m+2}; \mathbb{Q}) \times H_*(M; \mathbb{Q})^{m+2} \rightarrow \mathbb{Q},$$

the reader may refer to [14, 21] for details. (In the latter paper, we used the cohomology and denoted by $\mathcal{GW}$ the GW-invariants. It is easily translated into the homology while M is a closed manifold.) We also define

$$(4.7) \quad \text{GW}(M, \omega; \alpha_0, \alpha_\infty) := \inf \{ \text{GW}_g(M, \omega; \alpha_0, \alpha_\infty) \mid g \geq 0 \} \in [0, +\infty].$$

Based on [14], we proved in [23, Theorem 1.10] that

$$(4.8) \quad C_{HZ}^{(2)}(M, \omega; \alpha_0, \alpha_\infty) \leq \text{GW}(M, \omega; \alpha_0, \alpha_\infty),$$

$$(4.9) \quad C_{HZ}^{(2\circ)}(M, \omega; \alpha_0, \alpha_\infty) \leq \text{GW}_0(M, \omega; \alpha_0, \alpha_\infty)$$

for any closed symplectic manifold (M, ω) of dimension $\dim M \geq 4$ and homology classes $\alpha_0, \alpha_\infty \in H_*(M; \mathbb{Q}) \setminus \{0\}$. The following proposition lists partial results in [23, Proposition 1.7], which are needed in the following arguments.

Proposition 4.1. *Let $W \subset \text{Int}(M)$ be a smooth compact submanifold of codimension zero and with connected boundary such that the homology classes $\alpha_0, \alpha_\infty \in H_*(M; \mathbb{Q}) \setminus \{0\}$ have representatives supported in $\text{Int}(W)$ and $\text{Int}(M) \setminus W$, respectively. Denote by $\tilde{\alpha}_0 \in H_*(W; \mathbb{Q})$ and $\tilde{\alpha}_\infty \in H_*(M \setminus W; \mathbb{Q})$ the nonzero homology classes determined by them. Then*

$$(4.10) \quad C_{HZ}^{(2)}(W, \omega; \tilde{\alpha}_0, pt) \leq C_{HZ}^{(2)}(M, \omega; \alpha_0, \alpha_\infty)$$

and, in particular, one has

$$(4.11) \quad c_{HZ}(W, \omega) = C_{HZ}^{(2)}(W, \omega) \leq C_{HZ}^{(2)}(M, \omega; pt, \alpha)$$

for any $\alpha \in H_*(M; \mathbb{Q}) \setminus \{0\}$ with representative supported in $\text{Int}(M) \setminus W$. If the inclusion $W \hookrightarrow M$ induces an injective homomorphism $\pi_1(W) \rightarrow \pi_1(M)$, then

$$(4.12) \quad C_{HZ}^{(2\circ)}(W, \omega; \tilde{\alpha}_0, pt) \leq C_{HZ}^{(2\circ)}(M, \omega; \alpha_0, \alpha_\infty)$$

and corresponding to (4.11), one has

$$(4.13) \quad c_{HZ}^\circ(W, \omega) = C_{HZ}^{(2\circ)}(W, \omega) \leq C_{HZ}^{(2\circ)}(M, \omega; pt, \alpha).$$

We now construct a class of almost complex structures on $P(E \oplus \mathbb{C})$. The readers will see why we need Theorem 3.3. Note that every given Riemannian metric $P(E \oplus \mathbb{C})$ naturally restricts to a natural Riemannian metric g_b on the fibre $P(E \oplus \mathbb{C})_b$ for each $b \in B$. Using the standard method, (cf. [29, page 64]) one gets a compatible almost complex structure $J_b \in \mathcal{J}(P(E \oplus \mathbb{C})_b, (\omega_{FS})_b)$. Clearly, J_b smoothly depends on $b \in B$. Take another compatible almost complex structure $J_B \in \mathcal{J}(B, \beta)$. By (3.30), we can obtain its horizontal lift $\tilde{J}_B$ to $\mathcal{H}$:

$$(4.14) \quad (\tilde{J}_B)_x : \mathcal{H}_x \rightarrow \mathcal{H}_x, \quad X \mapsto (d\mathcal{P}(x))^{-1} \circ (J_B)_b \circ d\mathcal{P}(x)(X),$$

where $b = \mathcal{P}(x)$. Then using the decomposition (3.29), we may define an almost complex structure $\mathbf{J}$ on $P(E \oplus \mathbb{C})$ as follows:

$$(4.15) \quad \begin{aligned} \mathbf{J}_x : T_x P(E \oplus \mathbb{C}) = \mathcal{H}_x \oplus \mathcal{V}_x &\rightarrow T_x P(E \oplus \mathbb{C}), \\ X^h \oplus X^v &\mapsto (\tilde{J}_B)_x(X^h) \oplus (J_b)_x(X^v). \end{aligned}$$

Lemma 4.2. $\mathbf{J}$ is $\Omega_{A\varepsilon}^t$ -tamed for sufficiently small $t > 0$.

Proof. For any nonzero $X = X^h + X^v \in T_x P(E \oplus \mathbb{C}) = \mathcal{H}_x \oplus \mathcal{V}_x$, the direct computation yields

$$(4.16) \quad \begin{aligned} \Omega_{A\varepsilon}^t(X, \mathbf{J}X) &= \Omega_{A\varepsilon}^t(X^h + X^v, (\tilde{J}_B)_x X^h + (J_b)_x X^v) \\ &= \mathcal{P}^* \beta(X^h + X^v, (\tilde{J}_B)_x X^h + (J_b)_x X^v) \\ &\quad + t \Gamma_{A\varepsilon}(X^h + X^v, (\tilde{J}_B)_x X^h + (J_b)_x X^v) \\ &= \beta(d\mathcal{P}(x)(X^h), d\mathcal{P}(x)((\tilde{J}_B)_x X^h)) \\ &\quad + t \Gamma_{A\varepsilon}(X^h, (\tilde{J}_B)_x X^h) + t \varepsilon(\omega_{FS})_b(X^v, (J_b)_x X^v) \\ &\quad + t \Gamma_{A\varepsilon}(X^h, (J_b)_x X^v) + t \Gamma_{A\varepsilon}(X^v, (\tilde{J}_B)_x X^h) \\ &= \beta(d\mathcal{P}(x)(X^h), (J_B)_b d\mathcal{P}(x)X^h) \\ &\quad + t \Gamma_{A\varepsilon}(X^h, (\tilde{J}_B)_x X^h) + t \varepsilon(\omega_{FS})_b(X^v, (J_b)_x X^v). \end{aligned}$$

Here $\Gamma_{A\varepsilon}(X^h, (J_b)_x X^v) = 0$ and $\Gamma_{A\varepsilon}(X^v, (\tilde{J}_B)_x X^h) = 0$ are because of $(J_b)_x X^v \in \mathcal{V}_x$, $(\tilde{J}_B)_x X^h \in \mathcal{H}_x$ and the equality above (3.29), that is, $\mathcal{H}_x = \{X \in T_x P(E \oplus \mathbb{C}) \mid \Gamma_{A\varepsilon}(X, Y) = 0 \ \forall Y \in \mathcal{V}_x\}$. Since $P(E \oplus \mathbb{C})$ is compact, and by (3.30) the projection

$d\mathcal{P}(x)$ is a bijection, it easily follows that for a given $\epsilon \in (0, 1)$, there exists a $0 < \bar{t} \leq t_0$ such that

$$(4.17) \quad \begin{aligned} & \beta(d\mathcal{P}(x)(X^h), (J_B)_b d\mathcal{P}(x)X^h) + t\Gamma_{A\epsilon}(X^h, (\tilde{J}_B)_x X^h) \\ & \geq (1 - \epsilon)\beta(d\mathcal{P}(x)(X^h), (J_B)_b d\mathcal{P}(x)X^h) \end{aligned}$$

for all $t \in (0, \bar{t}]$ and any $X \in TP(E \oplus \mathbb{C})$. Note that J_b is compatible with $(\omega_{FS})_b$. The desired claim is proved. $\square$

Note that the almost complex structure $\mathbf{J}$ in (4.15) satisfies $d\mathcal{P} \circ \mathbf{J} = J_B \circ d\mathcal{P}$. That is, the projection $\mathcal{P}$ is holomorphic with respect to the almost complex structures $\mathbf{J}$ and J_B . In terms of [27, Definition 2.8], we say that the almost complex structure $\mathbf{J}$ on $P(E \oplus \mathbb{C})$ is *fibred* with respect to J_B . For such an almost complex structure $\mathbf{J}$ on $P(E \oplus \mathbb{C})$, any $\mathbf{J}$ -holomorphic curve in $P(E \oplus \mathbb{C})$ representing a homology class of fiber must sit entirely in a fiber. By the following remark, each J_b can be chosen as a canonical one such that for the corresponding almost complex structure $\mathbf{J}$, the projection $\mathcal{P} : (P(E \oplus \mathbb{C}), \mathbf{J}) \rightarrow (B, J_B)$ is an *almost complex fibration with fibre* $(\mathbb{C}P^n, J_{FS})$ in the sense of [1, Definition 6.3.A].

Remark 4.3. The above almost complex structure $J_b \in \mathcal{J}(P(E \oplus \mathbb{C})_b, (\omega_{FS})_b)$ can be chosen as canonical one as done in [1]. Namely, a Hermitian vector bundle may yield a canonical (almost) complex structure on each fibre of its projective bundle. For every $J_E \in \mathcal{J}(E, \bar{\omega})$, one has a corresponding almost complex structure on $P(E)$, J_{can} which restricts to an almost complex structure $J_{\text{can},b}$ on $P(E)_b = P(E_b)$ for each $b \in B$.

Recall that in [23, Definition 1.14], a closed symplectic manifold (M, ω) is called *g-symplectic uniruled* if the Gromov-Witten invariants

$$(4.18) \quad \Psi_{A,g,m+2}(C; pt, \alpha, \beta_1, \dots, \beta_m) \neq 0$$

for some homology classes $A \in H_2(M; \mathbb{Z})$, $\alpha, \beta_1, \dots, \beta_m \in H_*(M; \mathbb{Q})$ and $C \in H_*(\overline{\mathcal{M}}_{g,m+2}; \mathbb{Q})$ and an integer $m \geq 1$. In particular, if C can be chosen as the class of a point, (M, ω) is said to be *strong g-symplectic uniruled*.

Theorem 4.4. *Under the assumptions of Theorem 3.3, for the symplectic forms $\Omega_{A\epsilon}^t$ in (3.23), it holds that every symplectic manifold $(P(E \oplus \mathbb{C}), \Omega_{A\epsilon}^t)$ is strong 0-symplectic uniruled. More precisely, the GW-invariant*

$$(4.19) \quad \Psi_{L,0,3}(pt; pt, Z_0, Z_\infty) = 1,$$

where L denotes the class of the line in the fiber of $P(E \oplus \mathbb{C})$.

We put off its proof to the end of this paper.

Theorem 4.5. *Under the assumptions of Theorem 4.4, the pseudo symplectic capacity*

$$(4.20) \quad C_{HZ}^{(2\circ)}(P(E \oplus \mathbb{C}), \Omega_{A\varepsilon}^t; pt, Z_0) \leq \pi t \varepsilon^2$$

for each $0 < \varepsilon < \varepsilon_0(A, \mathcal{F})$ and $0 < t < t_0(A, \varepsilon)$. In particular, the π_1 -sensitive Hofer-Zehnder capacity

$$(4.21) \quad c_{HZ}^\circ(D_\varepsilon(E), \bar{\omega}_A^t) = c_{HZ}^\circ(D_1(E), \omega_{A\varepsilon}^t) \leq \pi t \varepsilon^2$$

for each $0 < \varepsilon < \varepsilon_0(\mathcal{F}, A)$ and $0 < t < t_0(A, \varepsilon)$. Furthermore, for a given connection form A' on $U(E)$ which is flat near some symplectically embedded ball in (B, β) of radius being the symplectic radius of (B, β) , and each

$$(4.22) \quad 0 < \varepsilon \ll \min\{\varepsilon_0(\mathcal{F}, A), \varepsilon_0(\mathcal{F}, A'), \varepsilon_0(P, A_{\text{can}}), \sqrt{\frac{\mathcal{W}_G(B, \beta)}{\pi}}\},$$

it holds that

$$(4.23) \quad c(D_\varepsilon(E), \bar{\omega}_A^t) = c(D_1(E), \omega_{A\varepsilon}^t) = \pi t \varepsilon^2$$

for each $0 < t < \min\{t_0(A', \varepsilon), t_0(A, \varepsilon)\}$ and $c = \mathcal{W}_G, c_{HZ}$, and c_{HZ}° .

Proof. Step 1. Proving (4.21). Firstly, note that (4.9) and (4.19) directly yields (4.20) because $\Omega_{A\varepsilon}^t(L) = \pi t \varepsilon^2$. Next, by Theorem 3.3(v), we have

$$(4.24) \quad c_{HZ}^\circ(D_\varepsilon(E), \bar{\omega}_A^t) = c_{HZ}^\circ(D_1(E), \omega_{A\varepsilon}^t)$$

for any $0 < \varepsilon < \varepsilon_0(A, \mathcal{F})$ and $0 < t < t_0(A, \varepsilon)$. By the exact homotopy sequence of the fibration, we can easily derive that the embedding $\varphi_{\mathcal{P}} : D_\delta(E) \rightarrow P(E \oplus \mathbb{C})$ induces an injective homomorphism $\pi_1(D_\delta(E)) \rightarrow \pi_1(P(E \oplus \mathbb{C}))$ for any $0 < \delta < 1$. Applying (4.13) to $W_\delta := \varphi_{\mathcal{P}}(Cl(D_\delta(E)))$, we get

$$(4.25) \quad C_{HZ}^\circ(W_\delta, \Omega_{A\varepsilon}^t) \leq C_{HZ}^\circ(P(E \oplus \mathbb{C}), \Omega_{A\varepsilon}^t; pt, Z_0) \leq \pi t \varepsilon^2$$

for any $0 < \varepsilon < \varepsilon_0(\mathcal{F}, A)$ and $0 < t < t_0(A, \varepsilon)$. Here the second inequality comes from (4.20). Note that (4.4) and Theorem 3.3(ii) imply

$$(4.26) \quad c_{HZ}^\circ(Cl(D_\delta(E)), \omega_{A\varepsilon}^t) = C_{HZ}^\circ(Cl(D_\delta(E)), \omega_{A\varepsilon}^t) = C_{HZ}^\circ(W_\delta, \Omega_{A\varepsilon}^t),$$

for each $0 < \varepsilon < \varepsilon_0(\mathcal{F}, A)$ and $0 < t < t_0(A, \varepsilon)$. Setting $\delta \rightarrow 1$ and using the definition of c_{HZ}° , we obtain that

$$(4.27) \quad c_{HZ}^\circ(D_1(E), \omega_{A\varepsilon}^t) \leq \pi t \varepsilon^2$$

for each $0 < \varepsilon < \varepsilon_0(\mathcal{F}, A)$ and $0 < t < t_0(A, \varepsilon)$. Now the desired (4.21) follows from (4.24) and (4.27) directly.

Step 2. Proving (4.23). Let $\dim B = 2k$. Take a symplectic embedding $\Upsilon : (B^{2k}(r), \omega_{\text{std}}) \rightarrow (B, \beta)$, where $r = \mathcal{W}_G(B, \beta)$ is the Gromov symplectic radius. Since $U(E)|_{\Upsilon(B^{2k}(r))}$ can be trivialized, for any small $\epsilon > 0$, we may choose a connection form A' on $U(E)$ such that it is *flat* near $\Delta := Cl(\Upsilon(B^{2k}(r - \epsilon)))$. By Theorem 3.3(vii), for any $0 < \varepsilon \ll \min\{\varepsilon_0(\mathcal{F}, A), \varepsilon_0(\mathcal{F}, A')\} \leq 1$, $0 < t < \min\{t_0(A, \varepsilon), t_0(A', \varepsilon)\}$, and $\delta \in (0, 1]$, we have a symplectomorphism

$$(4.28) \quad \varphi_\varepsilon^\delta : (D_\delta(E), \omega_{A\varepsilon}^t) \rightarrow (D_\delta(E), \omega_{A'\varepsilon}^t),$$

which is also a bundle isomorphism. Note that Δ has the same dimension as B . From the first paragraph of the proof of Theorem 3.2, it is easily observed that $\varepsilon_0^\circ(A'|_{Cl(\Delta)}, \mathcal{F}|_{U(E)|_{Cl(\Delta)}})$ can be taken as $\varepsilon_0(A', \mathcal{F})$. Hence, Theorem 3.3(vi) implies that $(D_1(E)|_\Delta, \omega_{A'\varepsilon}^t|_\Delta) = (D_1(E)|_\Delta, \omega_{A'\varepsilon}^t|_\Delta)$ is a symplectic submanifold in $(D_1(E), \omega_{A'\varepsilon}^t)$ for each $0 < \varepsilon < \varepsilon_0(A', \mathcal{F})$ and $0 < t < t_0(A', \varepsilon)$. So for any symplectic capacity c (including c_{HZ}°), it holds that

$$(4.29) \quad c(D_1(E)|_\Delta, \omega_{A'\varepsilon}^t|_\Delta) \leq c(D_1(E), \omega_{A'\varepsilon}^t).$$

By Theorem 3.3(v), the symplectomorphism

$$(4.30) \quad \psi_\varepsilon : (D_1(E), \omega_{A'\varepsilon}^t) \rightarrow (D_\varepsilon(E), \bar{\omega}_{A'}^t), \quad (b, v) \mapsto (b, \varepsilon v)$$

maps $(D_1(E)|_\Delta, \omega_{A'\varepsilon}^t|_\Delta) = (D_1(E)|_\Delta, \omega_{A'\varepsilon}^t|_\Delta)$ onto $(D_\varepsilon(E)|_\Delta, \bar{\omega}_{A'}^t|_\Delta)$. We get

$$(4.31) \quad c(D_1(E)|_\Delta, \omega_{A'\varepsilon}^t|_\Delta) = c(D_\varepsilon(E)|_\Delta, \bar{\omega}_{A'}^t|_\Delta)$$

for $0 < \varepsilon < \varepsilon_0(\mathcal{F}, A')$ and $0 < t < t_0(A', \varepsilon)$. Therefore (4.28), (4.29), and (4.31) yields

$$(4.32) \quad \begin{aligned} c(D_1(E), \omega_{A\varepsilon}^t) &= c(D_1(E), \omega_{A'\varepsilon}^t) \geq c(D_1(E)|_\Delta, \omega_{A'\varepsilon}^t|_\Delta) \\ &= c(D_\varepsilon(E)|_\Delta, \bar{\omega}_{A'}^t|_\Delta) \end{aligned}$$

for any $0 < \varepsilon \ll \min\{\varepsilon_0(\mathcal{F}, A), \varepsilon_0(\mathcal{F}, A')\} \leq 1$ and $0 < t < \min\{t_0(A, \varepsilon), t_0(A', \varepsilon)\}$. Now Theorem 3.3(viii) implies that for any $0 < \eta < \varepsilon_0(P, A_{\text{can}})$ and $t > 0$, the symplectic manifold $(D_\eta(E)|_\Delta, \bar{\omega}_{A'|_\Delta}^t)$ can be identified with

$$(4.33) \quad (\Delta \times B^{2n}(\eta), \beta \oplus (t\omega_{\text{std}}^{(n)})) \approx (Cl(B^{2k}(r - \epsilon)) \times B^{2n}(\eta), \omega_{\text{std}}^{(k)} \oplus (t\omega_{\text{std}}^{(n)})).$$

So for $0 < t < \mathcal{W}_G(B, \beta)/\pi\eta^2$, it holds that

$$(4.34) \quad \begin{aligned} c(D_\eta(E)|_\Delta, \bar{\omega}_{A'|_\Delta}^t) &= c(\Delta \times B^{2n}(\eta), \beta \oplus (t\omega_{\text{std}}^{(n)})) \\ &= c(Cl(B^{2k}(r - \epsilon)) \times B^{2n}(\eta), \omega_{\text{std}}^{(k)} \oplus (t\omega_{\text{std}}^{(n)})) \\ &\geq \mathcal{W}_G(Cl(B^{2k}(r - \epsilon)) \times B^{2n}(\eta), \omega_{\text{std}}^{(k)} \oplus (t\omega_{\text{std}}^{(n)})) \\ &\geq \pi t \eta^2. \end{aligned}$$

Taking $\eta = \varepsilon \ll \min\{\varepsilon_0(\mathcal{F}, A), \varepsilon_0(\mathcal{F}, A'), \varepsilon_0(P, A_{\text{can}})\}$, (4.32) and (4.34) yield that

$$(4.35) \quad c(D_1(E), \omega_{A\varepsilon}^t) \geq \pi t \varepsilon^2$$

for any $0 < t < \min\{t_0(A', \varepsilon), t_0(A, \varepsilon), \mathcal{W}_G(B, \beta)/\pi\varepsilon^2\}$. Note that we can choose $\varepsilon > 0$ so small that $\mathcal{W}_G(B, \beta)/\pi\varepsilon^2 > 1$ and that we can also assume that $t_0(A', \varepsilon)$ and $t_0(A, \varepsilon)$ are no more than 1. The desired (4.23) immediately follow from (4.21) and (4.35). $\square$

Proof of Theorem 1.3. Clearly, (1.7) and (1.8) directly follow from (4.21) and (4.23), respectively. To get (1.9), for a given $\epsilon > 0$, we choose $t > 0$ so small that $\pi t \varepsilon^2 < \epsilon$. Consider the (disk) bundle isomorphism

$$(4.36) \quad \Theta_{t,\varepsilon} : D_{\sqrt{t\varepsilon}}(E) \rightarrow D_\varepsilon(E), (b, v) \mapsto (b, \frac{1}{\sqrt{t}}v).$$

Then $\Theta_{t,\varepsilon}^* \bar{\omega}_A^t$ restricts to $(\omega_{\text{std}})_b$ on each fibre $D_{\sqrt{t\varepsilon}}(E)_b$, and the zero section 0_E is also a symplectic submanifold in $(D_{\sqrt{t\varepsilon}}(E), \Theta_{t,\varepsilon}^* \bar{\omega}_A^t)$. Hence, the zero section 0_E has the symplectic normal bundle $(E, \bar{\omega})$ in $(D_{\sqrt{t\varepsilon}}(E), \Theta_{t,\varepsilon}^* \bar{\omega}_A^t)$. By the Weinstein's symplectic neighborhood theorem, there exists $0 < \eta \ll \varepsilon$ such that $(D_{\sqrt{t\eta}}(E), \Theta_{t,\varepsilon}^* \bar{\omega}_A^t)$ and thus $(D_\eta(E), \bar{\omega}_A^t) \subset (D_\varepsilon(E), \bar{\omega}_A^t)$ is symplectomorphic to an open neighborhood W of B in M . Then (1.9) easily follows from this and (1.8). $\square$

Proof of Theorem 4.4. Since the Gromov-Witten invariants are symplectic deformation invariants, it suffices to prove that (4.19) holds on $(P(E \oplus \mathbb{C}), \Omega_{A\varepsilon}^t)$ for sufficiently small $t > 0$. To this end, we need to construct a suitable $\Omega_{A\varepsilon}^t$ -tamed almost complex

structure on $P(E \oplus \mathbb{C})$. Using the standard complex structure i and symplectic structure on $\mathbb{C}$, we get a complex structure $J_E \oplus i$ on $E \oplus \mathbb{C}$ and the corresponding Hermitian structure. As in Remark 4.3, it in turn yields a complex structure on each fibre $P(E \oplus \mathbb{C})_b$ of $P(E \oplus \mathbb{C})$, still denoted by $J_{\text{can},b}$. One now has obvious Kähler identification $(P(E \oplus \mathbb{C})_b, (\omega_{\text{FS}})_b, J_{\text{can},b}) \equiv (\mathbb{C}P^n, \omega_{\text{FS}}, J_{\text{FS}})$. From it and any compatible almost complex structure $J_B \in \mathcal{J}(B, \beta)$ we can, as in (4.15), form an almost complex structure $\mathbf{J}$ on $P(E \oplus \mathbb{C})$ which is $\Omega_{A\varepsilon}^t$ -tamed for some sufficiently small $0 < t < t_0(A, \varepsilon)$. Moreover, the projection $\mathcal{P} : (P(E \oplus \mathbb{C}), \mathbf{J}) \rightarrow (B, J_B)$ is an almost complex fibration with fibre $(\mathbb{C}P^n, J_{\text{FS}})$ by the final sentence above Remark 4.3. It is well-known that $J_{\text{FS}} \in \mathcal{J}_{\text{reg}}(\mathbb{C}P^n, \omega_{\text{FS}})$, (cf. [28, Prop.7.4.3]). Let $[\mathbb{C}P^1] \in H_2(\mathbb{C}P^n, \mathbb{Z})$ denote the class of the line $\mathbb{C}P^1 \subset \mathbb{C}P^n$. It was proved in [34] that the Gromov-Witten invariant $\Psi_{[\mathbb{C}P^1], 0, 3}^{(\mathbb{C}P^n, \omega_{\text{FS}})}(pt; pt, pt, [\mathbb{C}P^{n-1}]) = 1$, where pt always denotes the class of a single point for different spaces, and $[\mathbb{C}P^{n-1}] \in H_{2n-2}(\mathbb{C}P^n, \mathbb{Z})$ is the class of the hyperplane $\mathbb{C}P^{n-1} \subset \mathbb{C}P^n$.

Note that Z_0 (resp., Z_∞) restricts to a single point (resp., the hyperplane $\mathbb{C}P^{n-1}$) on each fiber $P(E \oplus \mathbb{C})_b \equiv \mathbb{C}P^n$. If $L \in H_2(P(E \oplus \mathbb{C}), \mathbb{Z})$ denotes the class of the line in the fiber, for the fibred almost complex structure $\mathbf{J}$ just constructed and a given point $x \in P(E \oplus \mathbb{C})$, every $\mathbf{J}$ -holomorphic sphere of class L in $P(E \oplus \mathbb{C})$ passing x must sit in the fiber $P(E \oplus \mathbb{C})_b$ at $b = \mathcal{P}(x) \in B$. Therefore, there exists such a unique curve passing x and generically intersecting with Z_0 and Z_∞ . As expected, we arrive at (4.19) for $(P(E \oplus \mathbb{C}), \Omega_{A\varepsilon}^t)$. Actually, by [1, Proposition 6.3.B], the $\mathbf{J}$ is regular for the class L . So if $\mathcal{M}(P(E \oplus \mathbb{C}), L, \mathbf{J})$ is the space of all $\mathbf{J}$ -holomorphic spheres in $P(E \oplus \mathbb{C})$ representing the class L , then $\mathcal{M}(P(E \oplus \mathbb{C}), L, \mathbf{J})/\text{PSL}(2, \mathbb{R})$ is a compact smooth manifold of dimension $\dim_{\mathbb{R}} B + 2\text{rank}_{\mathbb{R}} E - 6$, and that the dimension condition

$$\begin{aligned} \deg[pt] + \deg[Z_0] + \deg[Z_\infty] &= \dim_{\mathbb{R}} P(E \oplus \mathbb{C}) + 2c_1(L) \\ (4.37) \qquad \qquad \qquad &= \dim_{\mathbb{R}} B + 2\text{rank}_{\mathbb{R}} E + 2 \end{aligned}$$

is satisfied. It easily follows that the Gromov-Witten invariant (in the sense of [34]) $\Psi_{L, 0, 3}(pt; pt, [Z_0], [Z_\infty]) = 1$.

Since our [23] follows [14], the GW-invariant in (4.19) is one constructed by Liu-Tian in [14] (also see [21] for details). Let $\Psi_{L, 0, 3}^{\text{vir}}(pt; pt, [Z_0], [Z_\infty])$ denote this GW-invariant constructed with the virtual moduli cycles. In the remainder of the paper we shall show that

it is also equal to 1. (Namely, while some GW-invariant can be simultaneously defined in the methods in [14, 34], they agree.) Instead of using the method in [18], we use the method of proof of [23, Proposition 7.6] to prove that the GW-invariant $\Psi_{L,0,3}^{\text{vir}}(pt; pt, [Z_0], [Z_\infty])$ in the sense of the general definition is also equal to 1. Let $\overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C}), L, \mathbf{J})$ be the space of all equivalence classes of all 3-pointed stable $\mathbf{J}$ -maps of genus zero and of class L in $\mathbf{P}(E \oplus \mathbb{C})$. Then each stable map $[\mathbf{f}] \in \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C}), L, \mathbf{J})$ has an image set contained in a single fiber of $\mathbf{P}(E \oplus \mathbb{C})$ since the image set is connected. Assume that $\text{Im}(\mathbf{f}) \subset \mathbf{P}(E \oplus \mathbb{C})_b$. This $[\mathbf{f}]$ may naturally be viewed as an element of $\overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C})_b, L_b, J_{\text{can},b})$, where L_b is the class of the line in $\mathbf{P}(E \oplus \mathbb{C})_b \equiv \mathbb{C}P^n$. Since $\Omega_{A\varepsilon}^t|_{\mathbf{P}(E \oplus \mathbb{C})_b} = t\varepsilon^2(\omega_{\text{FS}})_b$ and L_b is indecomposable with respect to $(\omega_{\text{FS}})_b$, by the proof of [23, Proposition 7.6], it is easily seen that $\overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C})_b, L_b, J_{\text{can},b})$ is a stratified smooth compact manifold (using the regularity of $J_{\text{can},b}$). More precisely,

$$(4.38) \quad \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C})_b, L_b, J_{\text{can},b}) = \bigcup_{i=1}^4 \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C})_b, L_b, J_{\text{can},b})_i,$$

where each stratum $\overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C})_b, L_b, J_{\text{can},b})_i$ is a smooth manifold, and

$$(4.39) \quad \begin{aligned} \dim \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C})_b, L_b, J_{\text{can},b})_1 &= 2n + 2(n + 1), \\ \dim \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C})_b, L_b, J_{\text{can},b})_2 &= 2n + 2(n + 1) - 4, \\ \dim \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C})_b, L_b, J_{\text{can},b})_3 &= 2n + 2(n + 1) - 6, \\ \dim \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C})_b, L_b, J_{\text{can},b})_4 &= 2n + 2(n + 1) - 6. \end{aligned}$$

So $\overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C}), L, \mathbf{J}) = \bigcup_{b \in B} \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C})_b, L_b, J_{\text{can},b})$ is also a stratified smooth compact manifold (with correct dimension because of the regularity of $\mathbf{J}$). That is,

$$(4.40) \quad \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C}), L, \mathbf{J}) = \bigcup_{i=1}^4 \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C}), L, \mathbf{J})_i,$$

where $\overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C}), L, \mathbf{J})_i = \bigcup_{b \in B} \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C})_b, L_b, J_{\text{can},b})_i$, $i = 1, 2, 3, 4$. Since each stable map $[\mathbf{f}] \in \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C}), L, \mathbf{J})$ has no free components, we have the following claim.

Claim 4.6. *A virtual moduli cycle of $\overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C}), L, \mathbf{J})$ can be taken as*

$$(4.41) \quad \overline{\mathcal{M}}_{0,3}(\mathbf{P}(E \oplus \mathbb{C}), L, \mathbf{J}) \rightarrow \mathcal{B}_{0,3,L}^{\mathbf{P}(E \oplus \mathbb{C})}, [\mathbf{f}] \mapsto [\mathbf{f}].$$

Once it is proved, then almost repeating the proof of [23, Proposition 7.6], we can obtain the desired (4.19):

$$(4.42) \quad \Psi_{L,0,3}^{\text{vir}}(pt; pt, [Z_0], [Z_\infty]) = \Psi_{L,0,3}(pt; pt, [Z_0], [Z_\infty]) = 1.$$

In order to prove Claim 4.6, as in the proof of [23, Proposition 7.6], each $[\mathbf{f}] \in \overline{\mathcal{M}}_{0,3}(\mathcal{P}(E \oplus \mathbb{C}), L, \mathbf{J})$ must be one of the following four cases.

- (i) The domain $\Sigma = \mathbb{C}P^1$, $z_i, i = 1, 2, 3$, are three distinct marked points on Σ , and $f : \Sigma \rightarrow \mathcal{P}(E \oplus \mathbb{C})$ is a J -holomorphic map of class L .
- (ii) The domain Σ has exactly two components $\Sigma_1 = \mathbb{C}P^1$ and $\Sigma_2 = \mathbb{C}P^1$ which have a unique intersecting point. $f|_{\Sigma_1}$ is nonconstant and Σ_1 only contains a marked point. $f|_{\Sigma_2}$ is constant and Σ_2 contains two marked points.
- (iii) The domain Σ has exactly two components $\Sigma_1 = \mathbb{C}P^1$ and $\Sigma_2 = \mathbb{C}P^1$ which have a unique intersecting point. $f|_{\Sigma_1}$ is nonconstant and Σ_1 contains no marked point. $f|_{\Sigma_2}$ is constant and Σ_2 contains three marked points.
- (iv) The domain Σ has exactly three components $\Sigma_1 = \mathbb{C}P^1$, $\Sigma_2 = \mathbb{C}P^1$, and $\Sigma_3 = \mathbb{C}P^1$. Σ_1 and Σ_2 (resp., Σ_2 and Σ_3) has only an intersecting point, and Σ_1 and Σ_3 has no intersecting point. $f|_{\Sigma_1}$ is nonconstant and Σ_1 contains no a marked point. $f|_{\Sigma_2}$ is constant and Σ_2 contains a marked point. $f|_{\Sigma_3}$ is constant and Σ_3 contains two marked points.

Note that in each case, the nonconstant $f|_{\Sigma_1}$ is simple, and thus somewhere injective. It follows that the automorphism group $\text{Aut}(\mathbf{f})$ of $\mathbf{f}$ is trivial though $[\mathbf{f}]$ might contain many representatives. Let $\mathcal{B}_{L,0,3}^{\mathcal{P}(E \oplus \mathbb{C})}$ be the set of equivalence classes of all 3-pointed stable $L^{k,p}$ -maps in $\mathcal{P}(E \oplus \mathbb{C})$ which represent class L , have genus 0 and domains that belong to the four types above. For $[\mathbf{f}] \in \overline{\mathcal{M}}_{0,3}(\mathcal{P}(E \oplus \mathbb{C}), L, \mathbf{J})$, let $\tilde{\mathbf{U}}_\delta(\mathbf{f}, H)$ be the local uniformizer near $[\mathbf{f}] \in \mathcal{B}_{L,0,3}^{\mathcal{P}(E \oplus \mathbb{C})}$ as constructed in [12, Section 2] (also see [21, Section 2] for details). Since $\text{Aut}(\mathbf{f})$ is trivial, [12, Lemma 2.6] showed that the natural projection $\tilde{\mathbf{U}}_\delta(\mathbf{f}, H) \rightarrow \mathcal{B}_{L,0,3}^{\mathcal{P}(E \oplus \mathbb{C})}$ gives rise to a homeomorphism to an open neighborhood of $[\mathbf{f}]$ in $\mathcal{B}_{L,0,3}^{\mathcal{P}(E \oplus \mathbb{C})}$ (see [27, Section 4.2.1] for more explanations). This suggests that some open neighborhood $\mathcal{W}$ of $[\mathbf{f}]$ in $\overline{\mathcal{M}}_{0,3}(\mathcal{P}(E \oplus \mathbb{C}), L, \mathbf{J})$ in $\mathcal{B}_{L,0,3}^{\mathcal{P}(E \oplus \mathbb{C})}$ might carry a stratified Banach manifold structure. Regardless of these, we still adopt the Liu-Tian construction method in [12, 14] to get a system of bundles

$$(4.43) \quad (\tilde{E}^\Gamma, \tilde{W}^\Gamma) = \{(\tilde{E}_I^{\Gamma_I}, \tilde{W}_I^{\Gamma_I}), \tilde{\pi}_I, \tilde{\Pi}_I, \Gamma_I, \tilde{\pi}_J^I, \tilde{\Pi}_J^I, \lambda_J^I \mid J \subset I \in \mathcal{N}\}$$

(cf. [21]). However, so far all $\tilde{E}_I^{\Gamma_I} \rightarrow \tilde{W}_I^{\Gamma_I}$ are stratified Banach bundles on stratified Banach manifolds, all groups Γ_I and homomorphisms λ_J^I are trivial, and all projections $\tilde{\pi}_I$, $\tilde{\Pi}_I$, $\tilde{\pi}_J^I$ and $\tilde{\Pi}_J^I$ becomes open embeddings. Therefore, it is not needed to make furthermore desingularization for the system of bundles in (4.43) as done in [13] (also see [21] for a detailed description). We only need to renormalize $(\tilde{\mathcal{E}}^\Gamma, \tilde{W}^\Gamma)$ to get a new system of stratified smooth Banach bundles

$$(4.44) \quad (\tilde{\mathcal{E}}, \tilde{V}) = \{(\tilde{E}_I, \tilde{V}_I), \tilde{\pi}_I, \tilde{\pi}_J^I, \tilde{\Pi}_I, \tilde{\Pi}_J^I, \tilde{p}_I, \Gamma_I \mid J \subset I \in \mathcal{N}\}$$

as in [12, 14]. Then by restrictions, we get a system of stratified smooth Banach bundles as in [21, (3.74)]:

$$(4.45) \quad (\tilde{\mathcal{E}}^*, \tilde{V}^*) = \{(\tilde{E}_I^*, \tilde{V}_I^*), \tilde{\pi}_I, \tilde{\pi}_J^I, \tilde{\Pi}_I, \tilde{\Pi}_J^I, \tilde{p}_I, \Gamma_I \mid J \subset I \in \mathcal{N}\}.$$

Now following the idea of the proof of [12, Theorem 4.1] (see [21, (3.75) and (3.76)]), we have the obvious pullback stratified smooth Banach bundle system

$$(4.46) \quad (\mathbf{P}_1^* \tilde{\mathcal{E}}^*, \tilde{V}^* \times \mathbf{B}_\eta(\mathbb{R}^q)) = \{(\mathbf{P}_1^* \tilde{E}_I^*, \tilde{V}_I^* \times \mathbf{B}_\eta(\mathbb{R}^q)), \pi_I, \pi_J^I, \Pi_I, \Pi_J^I, p_I, \Gamma_I \mid J \subset I \in \mathcal{N}\},$$

and its global section $\Psi = \{\Psi_I \mid I \in \mathcal{N}\}$,

$$(4.47) \quad \Psi_I : \tilde{V}_I^* \times \mathbf{B}_\eta(\mathbb{R}^q) \rightarrow \mathbf{P}_1^* \tilde{E}_I^*, (\tilde{x}_I, \mathbf{t}) \mapsto (\tilde{\partial}_{\mathbf{J}})_I(\tilde{x}_I) + \sum_{i=1}^{n_3} \sum_{j=1}^{q_i} t_{ij} (\tilde{s}_{ij})_I(\tilde{x}_I),$$

where $\mathbf{t} = \{t_{ij} \mid 1 \leq j \leq q_i, 1 \leq i \leq n_3\} \in \mathbb{R}^q$. Clearly, $\Psi_I(\tilde{x}_I, 0) = 0$ for any zero $\tilde{x}_I$ of $(\tilde{\partial}_{\mathbf{J}})_I$ in $\tilde{V}_I$. By [21, Theorem 3.14 and Corollary 3.15], we get a small $\eta > 0$ and a residual subset $\mathbf{B}_\eta^{res}(\mathbb{R}^q) \subset \mathbf{B}_\eta(\mathbb{R}^q)$ such that for each $\mathbf{t} \in \mathbf{B}_\eta^{res}(\mathbb{R}^q)$, the global section $\Psi^{(\mathbf{t})} = \{\Psi_I^{(\mathbf{t})} \mid I \in \mathcal{N}\}$ of the bundle system $(\tilde{\mathcal{E}}^*, \tilde{V}^*)$ is transversal to the zero section, where $\Psi_I^{(\mathbf{t})} : \tilde{V}_I^* \rightarrow \tilde{E}_I^*$, $\tilde{x}_I \mapsto \Psi_I(\tilde{x}_I, \mathbf{t})$. So the set $\tilde{\mathcal{M}}_I^{\mathbf{t}} := (\Psi_I^{(\mathbf{t})})^{-1}(0)$ is a stratified smooth Banach manifold of dimension $\dim B + 4n + 2$. It also holds that

- (A) the stratified Banach manifold $\tilde{\mathcal{M}}_I^{\mathbf{t}}$ has no strata of codimension odd, and each stratum of $\tilde{\mathcal{M}}_I^{\mathbf{t}}$ of codimension r is exactly the intersection of $\tilde{\mathcal{M}}_I^{\mathbf{t}}$ and the stratum of $\tilde{V}_I^*$ of codimension r for $r = 0, \dots, \dim B + 4n + 2$;
- (B) the family $\tilde{\mathcal{M}}^{\mathbf{t}} = \{\tilde{\mathcal{M}}_I^{\mathbf{t}} \mid I \in \mathcal{N}\}$ is compatible in the sense that for any $J \subset I \in \mathcal{N}$,

$$(4.48) \quad \tilde{\pi}_J^I : (\tilde{\pi}_J^I)^{-1}(\tilde{\mathcal{M}}_I^{\mathbf{t}}) \rightarrow \text{Im}(\tilde{\pi}_J^I) \subset \tilde{\mathcal{M}}_J^{\mathbf{t}}$$

is a continuous and stratified smooth open embedding;

- (C) for each $I \in \mathcal{N}$ and any two $\mathbf{t}, \mathbf{t}' \in \mathbf{B}_\eta^{\text{res}}(\mathbb{R}^q)$, the cornered stratified Banach manifolds $\widetilde{\mathcal{M}}_I^{\mathbf{t}}$ and $\widetilde{\mathcal{M}}_I^{\mathbf{t}'}$ are cobordant, and thus maps $\tilde{\pi}_I : \widetilde{\mathcal{M}}_I^{\mathbf{t}} \rightarrow \mathcal{W}$ and $\tilde{\pi}_I : \widetilde{\mathcal{M}}_I^{\mathbf{t}'} \rightarrow \mathcal{W}$ are also cobordant.

Since $|\Gamma_I| = 1$ for any $I \in \mathcal{N}$, the formal summations

$$(4.49) \quad \mathcal{C}^{\mathbf{t}} := \sum_{I \in \mathcal{N}} \{\tilde{\pi}_I : \widetilde{\mathcal{M}}_I^{\mathbf{t}} \rightarrow \mathcal{W}\} \quad \forall \mathbf{t} \in \mathbf{B}_\varepsilon^{\text{res}}(\mathbb{R}^q),$$

a family of cobordant singular cycles in $\mathcal{W}$, are virtual moduli cycles in $\mathcal{W}$ constructed by Liu-Tian method (cf. [12, 13, 14, 21]). As explained [12, page 65], the summation precisely means that on the overlap of two pieces of $\mathcal{C}^{\mathbf{t}}$, we only count them once. Since all $\tilde{\pi}_I$ and $\tilde{\pi}_J^I$ are stratified smooth open embeddings, $\{(\tilde{\pi}_I, \mathcal{M}_I^{\mathbf{t}}) \mid I \in \mathcal{N}\}$ is actually a compatible coordinate chart cover of a compact, stratified smooth Banach manifold $\cup_{I \in \mathcal{N}} \tilde{\pi}_I(\mathcal{M}_I^{\mathbf{t}}) \subset \mathcal{W}$ of dimension $\dim B + 4n + 2$ and without strata of codimension one.

Note that each $(\tilde{\partial}_{\mathbf{J}})_I$ is essentially the Cauchy-Riemann operator $\bar{\partial}_{\mathbf{J}}$ and that $\mathbf{J}$ is regular with respect to the class L . It is not hard to prove that $\mathbf{0} \in \mathbf{B}_\varepsilon^{\text{res}}(\mathbb{R}^q)$ and $\cup_{I \in \mathcal{N}} \tilde{\pi}_I(\widetilde{\mathcal{M}}_I^{\mathbf{0}}) = \overline{\mathcal{M}}_{0,3}(\mathcal{P}(E \oplus \mathbb{C}), L, \mathbf{J})$. This proved Claim 4.6. $\square$

Remark 4.7. As suggested in the above proof, so far $\mathcal{E} \rightarrow \mathcal{W}$ might be a stratified Banach bundle on a stratified Banach manifold. The Cauchy-Riemann operator $\bar{\partial}_{\mathbf{J}}$ is a Fredholm section (restricting each stratum) and has $\overline{\mathcal{M}}_{0,3}(\mathcal{P}(E \oplus \mathbb{C}), L, \mathbf{J})$ as zero set of it. The original arguments of transversality and gluing may yield finitely many continuous stratified smooth sections $s_i : \mathcal{W} \rightarrow \mathcal{E}$, $i = 1, \dots, m$ such that the section

$$(4.50) \quad \Phi : \mathcal{W} \times \mathbf{B}_\eta(\mathbb{R}^m) \rightarrow \Pi_1^* \mathcal{E}, \quad (\tau, \mathbf{t}) \mapsto \bar{\partial}_{\mathbf{J}} \tau + t_1 s_1(\tau) + \dots + t_m s_m(\tau)$$

is transversal to the zero section for $\eta > 0$ small enough. Consequently, for generic small $\mathbf{t} \in \mathbf{B}_\eta(\mathbb{R}^m)$, the section $\Phi_{\mathbf{t}} : \mathcal{W} \rightarrow \mathcal{E}$, $\tau \mapsto \bar{\partial}_{\mathbf{J}} \tau + t_1 s_1(\tau) + \dots + t_m s_m(\tau)$ is transversal to the zero section. In particular, since $\mathbf{J}$ is regular, the section $\Phi_0 = \bar{\partial}_{\mathbf{J}}$ is transversal to the zero section. So we do not need to use Liu-Tian method as above and can construct a desired perturbation cycle of $\overline{\mathcal{M}}_{0,3}(\mathcal{P}(E \oplus \mathbb{C}), L, \mathbf{J})$, which is cobordant to virtual moduli cycles constructed by Liu-Tian method. These are, in detail, explained and developed in general abstract settings in [24].

Acknowledgements. This work was partially supported by the NNSF 10371007 of China and the Program for New Century Excellent Talents of the Education Ministry of China. This work began during the author's visit at the Institut des Hautes Études Scientifiques (IHES) in Winter 2004 and was completed during the author's visit to the Abdus Salam International Centre for Theoretical Physics in Summer 2005. The author cordially thanks Professors J. P. Bourguignon and D.T. Lê for their invitations and for the financial support and hospitality of their institutions, and Professor C. Viterbo for his invitation to join Symplectic Geometry Seminar in École Polytechnique during the author's visit to IHES in Winter 2004. The author also thanks Paul Biran, Leonardo Macarini, Felix Schlenk and Ramadas Ramakrishnan for some related discussions. The author would like to thank Professor Leonid Polterovich for mailing me his lovely book [33] and for very valuable improvement suggestions, and he would like to thank Ely Kerman for sending me his preprint. Thanks are also due to the anonymous referee, whose comments and corrections improved the exposition.
